eviCore healthcare Clinical Decision Support Tool Diagnostic Strategies: This tool addresses common symptoms and symptom complexes. Imaging requests for individuals with atypical symptoms or clinical presentations that are not specifically addressed will require physician review. Consultation with the referring physician, specialist and/or individual's Primary Care Physician (PCP) may provide additional insight.

PEDCH-1.1: Pediatric Chest Imaging Age Considerations

- Many conditions affecting the chest in the pediatric population are different diagnoses than those occurring in the adult population. For those diseases which occur in both pediatric and adult populations, differences may exist in management due to patient age, comorbidities, and differences in disease natural history between children and adults.
- Patients who are <18 years old should be imaged according to the Pediatric Chest Imaging Guidelines, and patients who are ≥18 years old should be imaged according to the Adult Chest Imaging Guidelines, except where directed otherwise by a specific guideline section.

PEDCH-1.2: Pediatric Chest Imaging Appropriate Clinical Evaluation

- A recent (within 60 days) face to face evaluation including a detailed history, physical examination, and appropriate laboratory studies should be performed prior to considering advanced imaging (CT, MRI, Nuclear Medicine), unless the patient is undergoing guideline-supported scheduled follow-up imaging evaluation.
- Unless otherwise stated in a specific guideline section, the use of advanced imaging to screen asymptomatic patients for disorders involving the chest is not supported. Advanced imaging of the chest should only be approved in patients who have documented active clinical signs or symptoms of disease involving the chest.
- Unless otherwise stated in a specific guideline section, repeat imaging studies of the chest are not necessary unless there is evidence for progression of disease, new onset of disease, and/or documentation of how repeat imaging will affect patient management or treatment decisions.

PEDCH-1.3: Pediatric Chest Imaging Modality General Considerations

- MRI
  - MRI Chest is generally performed without and with contrast (CPT® 71552) unless the patient has a documented contraindication to gadolinium or otherwise stated in a specific guideline section.
  - Due to the length of time required for MRI acquisition and the need to minimize patient movement, anesthesia is usually required for almost all infants (except neonate) and young children (age <7 years), as well as older children with delays in development or maturity. This anesthesia may be administered via oral or intravenous routes. In this patient population, MRI sessions should be planned with a goal of minimizing anesthesia exposure by adhering to the following considerations:
    - MRI procedures can be performed without and/or with contrast use as supported by these condition-based guidelines. If intravenous access will already be present for anesthesia administration and there is no contraindication for using contrast, imaging without and with contrast may be appropriate if requested. By doing so, the requesting provider may avoid repetitive anesthesia administration to perform an MRI with contrast if the initial study without contrast is inconclusive.
Recent evidence-based literature demonstrates the potential for gadolinium deposition in various organs including the brain, after the use of MRI contrast.

The U.S. Food and Drug Administration (FDA) has noted that there is currently no evidence to suggest that gadolinium retention in the brain is harmful and restricting gadolinium-based contrast agents (GBCAs) use is not warranted at this time. It has been recommended that GBCA use should be limited to circumstances in which additional information provided by the contrast agent is necessary and the necessity of repetitive MRIs with GBCAs should be assessed.

- If multiple body areas are supported by eviCore guidelines for the clinical condition being evaluated, MRI of all necessary body areas should be obtained concurrently.
- The presence of surgical hardware or implanted devices may preclude MRI.
- The selection of best examination may require coordination between the provider and the imaging service.

**CT**

- CT Chest is generally performed either with contrast (CPT® 71260) or without contrast (CPT® 71250).
  - There are no generally accepted pediatric indications for CT Chest without and with contrast (CPT® 71270).
  - CT should not be used to replace MRI in an attempt to avoid sedation unless listed as a recommended study in a specific guideline section.
  - The selection of best examination may require coordination between the provider and the imaging service.

**Ultrasound**

- Ultrasound chest (CPT® 76604) or axilla (CPT® 76882) is indicated as an initial study for evaluating adenopathy, palpable chest wall lesions, pleural effusion or thickening, patency of thoracic vasculature, and diaphragm motion abnormalities.
- For those patients who do require advanced imaging, ultrasound can be very beneficial in selecting the proper modality, body area, image sequences, and contrast level that will provide the most definitive information for the patient.

**Nuclear Medicine**

- Nuclear medicine studies other than PET/CT are rarely used in evaluation of the pediatric chest.
- Pulmonary Ventilation-Perfusion Imaging (CPT® 78582) has been replaced by CTA Chest (CPT® 71275) or CT Chest with contrast (CPT® 71260), but can be approved for evaluation of suspected pulmonary embolism if CT is unavailable.
  - See CH-25: Pulmonary Embolism (PE) in the Chest Imaging Guidelines.
- Pulmonary Perfusion Imaging (CPT® 78580) should generally not be approved in lieu of CPT® 78582 for initial evaluation of suspected pulmonary embolism, but can be approved for follow up of an equivocal or positive recent ventilation-perfusion lung scan (CPT® 78582) to evaluate for interval change.
Pulmonary Ventilation Imaging (CPT® 78579) should not be approved in lieu of CPT® 78582 for evaluation of suspected pulmonary embolism, but can be approved for additional evaluation of an abnormal perfusion-only scan (CPT® 78580).

Pulmonary split crystal function study (CPT® 78597 or CPT® 78598), also known as Quantitative Differential Pulmonary Perfusion, is indicated for preoperative planning of segmental, lobar, or lung resection.

Quantitative Differential Pulmonary Perfusion Lung Scan (CPT® 78597 or CPT® 78598), can be performed for post lung transplant patients to detect regional perfusion abnormalities.

Radiopharmaceutical nuclear medicine imaging of an inflammatory process (CPT® 78805, CPT® 78806, or CPT® 78807) is rarely performed, but is indicated for evaluation of sarcoidosis or toxicity from drug toxicity (cyclophosphamide, busulfan, bleomycin, amiodarone, or nitrofurantoin).

The guidelines listed in this section for certain specific indications are not intended to be all-inclusive; clinical judgment remains paramount and variance from these guidelines may be appropriate and warranted for specific clinical situations.

**PEDCH-2: Lymphadenopathy**

- Axillary lymphadenopathy imaging indications in pediatric patients are identical to those for adult patients. See **CH-2.2: Axillary Lymphadenopathy (and Mass)** in the Chest Imaging Guidelines.

- Supraclavicular adenopathy in pediatric patients is almost always pathologic, and advanced imaging is indicated prior to excisional biopsy. Fine needle aspiration, while common in adults prior to advanced imaging, is inappropriate for evaluating lymphadenopathy in pediatric patients. Any of the following studies may be approved for evaluation of supraclavicular adenopathy in children:
  - CT Chest with contrast (CPT® 71260).
  - MRI Chest without and with contrast (CPT® 71552).
  - Ultrasound chest (CPT® 76604).

- If malignancy is suspected, see the appropriate imaging guidelines as below:
  - Lymphoma: **PEDONC-5: Pediatric Lymphomas** in the Pediatric Oncology Imaging Guidelines.
  - Soft tissue sarcoma: **PEDONC-8: Pediatric Soft Tissue Sarcomas** in the Pediatric Oncology Imaging Guidelines.
  - Neuroblastoma: **PEDONC-6: Neuroblastoma** in the Pediatric Oncology Imaging Guidelines.

**Reference**

**PEDCH-3: Mediastinal Mass**

The causes of mediastinal masses in children are generally different than those in adults, and the imaging considerations are different.

- Chest x-ray is indicated as an initial study for all patients with suspected mediastinal mass.
- CT Chest with contrast (CPT® 71260) is indicated for any pediatric patient with a mediastinal mass identified on Chest x-ray.
  - Masses can be very large and anterior masses frequently cause compression of the trachea and/or mediastinal blood vessels.
- MRI Chest without and with contrast (CPT® 71552) is indicated for any pediatric patient with:
  - A posterior (paravertebral) mediastinal mass on CT Chest that invades the spinal canal.
  - CT findings are inconclusive regarding specific anatomy.
  - MRI should not be used for patients with large anterior mediastinal masses if anesthesia is necessary to complete the study.
- PET/CT (CPT® 78815) is indicated prior to biopsy in pediatric patients if lymphoma is known or strongly suspected or there is evidence of tracheal compression on CT imaging. See **PEDONC-5: Pediatric Lymphoma** in the Pediatric Oncology Imaging Guidelines.
- MIBG (CPT® 78804) is indicated and can be approved prior to biopsy in pediatric patients if neuroblastoma is known or strongly suspected. See **PEDONC-6: Neuroblastoma** in the Pediatric Oncology Imaging Guidelines.
- Ultrasound (CPT® 76604) can be approved in children younger than 5 years old to distinguish prominent but otherwise normal thymus from true mediastinal mass.
- A single repeat CT Chest with contrast (CPT® 71260) can be approved to confirm stability and avoid biopsy for patients with NONE of the following features:
  - Anterior mediastinal mass.
  - Enlarged lymph nodes anywhere in the imaging field.
  - Lymphopenia.
  - Pleural effusion.

**PEDCH-4.1: Hemoptysis – Imaging**

- True hemoptysis is rare in pediatric patients, and a detailed history, physical examination, and appropriate laboratory studies should be performed prior to considering advanced imaging.
  - Aspirated blood from epistaxis or emesis frequently presents as hemoptysis, and history and physical examination will aid in this assessment.
- Chest x-ray is indicated as an initial study for stable patients.
  - Advanced imaging is not indicated for patients with epistaxis and a normal chest radiograph and no personal or family history of underlying lung disease or bleeding disorder.
  - CT Chest with contrast (CPT® 71260) is indicated for all other pediatric patients with hemoptysis.
    - CT Chest without contrast (CPT® 71250) can be approved for patients with a documented allergy to CT contrast or significant renal dysfunction.
- MRI is not indicated in the evaluation of pediatric hemoptysis.

**PEDCH-5.1: Cystic Fibrosis**

- Chest x-ray is the primary study for initial evaluation of acute clinical symptoms in patients with cystic fibrosis.
- CT Chest without contrast (CPT® 71250) or with contrast (CPT® 71260) is indicated for the following (without initial Chest x-ray):
  - Hemoptysis.
  - Pneumonia worsening despite antibiotic therapy.
  - Pleural effusion or empyema.
  - Suspected fungal pneumonia.
  - Monitoring treatment changes on bronchiectasis.
  - Expiratory CT for evaluating small airways disease.
  - Pre- and post-lung transplant evaluation.
- Low dose CT Chest without contrast (CPT® 71250) is indicated every 2 years for monitoring of bronchiectasis and small airways disease.

**PEDCH-5.2: Bronchiectasis Not Associated with Cystic Fibrosis**

- Bronchiectasis not associated with cystic fibrosis is rare in pediatric patients, and imaging indications are identical to those for adult patients. See CH-7: Bronchiectasis in the Chest Imaging Guidelines.

**References**

PEDCH-6: Bronchiolitis

Bronchiolitis is a self-limiting viral infection causing inflammation of the small airways, most common in infants under 12 months of age.

- Chest x-rays are indicated when there is a clinical suspicion of pneumonia or other complications.
- Advanced imaging is not indicated for routine evaluation or monitoring of bronchiolitis, but CT Chest with contrast (CPT® 71260) can be approved for the following:
  - Pleural effusion or empyema on recent Chest x-ray.
  - Immunocompromised patient with acute pulmonary symptoms.
  - Abnormality on recent Chest x-ray suggesting condition other than bronchiolitis.

References
PEDCH-7: Pneumonia

> Pneumonia imaging indications in pediatric patients are very similar to those for adult patients. See CH-13: Pneumonia in the Chest Imaging Guidelines.

> Pediatric-specific imaging considerations include the following:
  - CT Chest with contrast (CPT® 71260) for immunocompromised patients with acute pulmonary symptoms.
  - CT Chest without contrast (CPT® 71250) or with contrast (CPT® 71260) for patients with recurrent lower respiratory tract infections.
  - Ultrasound chest (CPT® 76604) can be approved for evaluation of complicated or recurrent childhood pneumonia.

References

PEDCH-8: Solitary Pulmonary Nodule

The Fleischner Society guidelines for solitary pulmonary nodule management do not apply to pediatric patients. An incidental solitary pulmonary nodule in a child representing a primary lung carcinoma has never been reported in the literature. Similarly, an extrathoracic malignancy presenting with an incidental solitary pulmonary nodule in an otherwise healthy child is very rare.

- CT Chest with contrast (CPT® 71260) as a one-time evaluation for all children with a pulmonary nodule incidentally discovered on other imaging.
- Follow up imaging of incidental solitary pulmonary nodules in asymptomatic healthy children is not necessary.
  - Follow up imaging is indicated for the following:
    - Immunocompromised patients.
    - Malignancy (see below).
    - Invasive infection.
    - New or worsening pulmonary symptoms.
- Children with a malignant solid tumor who have pulmonary nodules of any size should have imaging according to the guideline section for the specific cancer type. See Pediatric Oncology Imaging Guidelines for specific imaging indications.
- This guideline section does not apply to multiple pulmonary nodules, which are imaged according to the underlying disorder in pediatric patients.

Practice Notes

A nodule is any pulmonary or pleural lesion that is a discrete, spherical opacity 2-30 mm in diameter surrounded by normal lung tissue. A larger nodule is called a mass. Entities that are not nodules, and are considered benign, include non-spherical linear, sheet-like, two-dimensional or scarring opacities.

References

PEDCH-9: Positive PPD or Tuberculosis

Positive PPD and tuberculosis imaging indications in pediatric patients are similar to those for adult patients. See CH-14.1: PPD or TB (Mycobacterium tuberculosis and Mycobacterium avium complex (MAC)) in the Chest Imaging Guidelines.

Pediatric-specific imaging considerations include the following:
- MRI Spine with and without contrast can be approved at symptomatic levels in patients with concern for spinal involvement of tuberculosis.

References
PEDCH-10: Asthma

- Chest x-ray is indicated when the patient’s condition does not respond to standard therapy, to identify complications, such as pneumonia or to rule out other causes of respiratory distress.

- Advanced imaging is not indicated for routine evaluation or monitoring of asthma, but CT Chest without (CPT® 71250) or with (CPT® 71260) contrast can be approved for the following:
  - Pleural effusion or empyema on recent Chest x-ray.
  - Immunocompromised patient with acute pulmonary symptoms.
  - Abnormality on recent Chest x-ray suggesting condition other than asthma, including suspected foreign body.
  - Asthma and poor response to bronchodilators or conventional inhaled corticosteroid therapy in whom associated conditions, such as allergic bronchopulmonary aspergillosis and eosinophilic pneumonia can mimic asthma.

References

Pediatric Chest Imaging

**PEDCH-11: Pectus Deformities**

- CT Chest without contrast (CPT® 71250), MRI Chest with and without contrast (CPT® 71552), or MRI Chest without contrast (CPT® 71550) is indicated in patients with a pectus deformity for:
  - Preoperative planning.
  - Significant cardiac displacement after Chest x-ray and echocardiography (CPT® 93306).
  - Evidence of pulmonary impingement after Chest x-ray and pulmonary function tests (PFTs) if there is increasing shortness of breath. **Note:** It may not be possible to obtain PFTs in children younger than 9 years old.
  - Evaluation of congenital heart disease or Marfan’s syndrome when suspected in those patients with pectus deformities.

PEDCH-12: Breast Masses

See PEDONC-17: Pediatric Breast Masses in the Pediatric Oncology Imaging Guidelines.
PEDCH-13: Vascular Malformations

PEDCH-13.1: Vascular Ring  23
PEDCH-13.2: Other Vascular Malformations  23
PEDCH-13.1: Vascular Ring

Vascular rings generally present with either respiratory symptoms (stridor, wheezing, tachypnea, cough) or feeding difficulties (dysphagia, slow feeding, hyperextension of the head while feeding, weight loss, failure to thrive) but can also be discovered incidentally on imaging obtained for other purposes.

- Chest x-ray is the recommended initial study in patients with respiratory symptoms.
- Barium esophagram is the recommended initial study in patients with feeding difficulties.
- CT Chest with contrast (CPT® 71260), CTA Chest (CPT® 71275) or MRA Chest (CPT® 71555) can be approved in patients with known or suspected vascular ring after Chest x-ray or barium esophagram.
- Echocardiogram can be approved to rule out associated congenital heart disease.
  - CPT® 93303, CPT® 93306, CPT® 93320, and CPT® 93325 can be approved for initial evaluation of patients with vascular ring and no prior echocardiograms.

PEDCH-13.2: Other Vascular Malformations

See PEDCH-14.2: Pulmonary Arteriovenous Malformations for Pulmonary AVMs.

</table>
**PEDCH-14.1: Congenital Cystic Lung Diseases**

- This section includes common congenital cystic lung lesions such as:
  - Bronchogenic cyst
  - Congenital pulmonary airway malformation (congenital cystic adenomatoid malformation)
  - Congenital lobar overinflation

- Cystic Lung disease may be first identified on prenatal ultrasound, or discovered incidentally on Chest x-ray.
- Chest x-ray is indicated before considering advanced imaging.
- CT Chest with contrast (CPT® 72160) may be approved when Chest x-ray suggests a cystic lung lesion.
- MRI Chest with and without contrast (CPT® 71552) can be approved if CT is inconclusive or if requested for pre-operative planning

**PEDCH-14.2: Pulmonary Arteriovenous Malformations**

- Pulmonary arteriovenous malformations (PAVMs) are vascular structures that most commonly result from abnormal communication between pulmonary arteries and pulmonary veins.
  - Chest x-ray are indicated as an initial imaging modality for patients with known AVMs, or patients presenting with hypoxemia and/or hemoptysis
  - CTA or MRA may be approved in patients with known AVM or abnormal Chest x-ray suggesting AVM for treatment planning

**References**
