Hemoglobinopathies Genetic Testing

Introduction

Testing for hemoglobinopathies is addressed by this guideline.

Procedures addressed

The inclusion of any procedure code in this table does not imply that the code is under management or requires prior authorization. Refer to the specific Health Plan's procedure code list for management requirements.

What are Hemoglobinopathies

Definition

Hemoglobinopathies are a group of genetic disorders involving abnormal production or structure of the hemoglobin protein.¹

Hemoglobin is found in red blood cells and is responsible for delivering oxygen throughout the body. It is composed of four polypeptide sub-units (globin chains) that normally associate with each other in one of the following forms:

- Hemoglobin A (HbA), composed of two alpha and two beta chains, makes up about 95-98% of adult hemoglobin.
- Hemoglobin A₂ (HbA₂), composed of two alpha and two delta chains, makes up about 2-3% of adult hemoglobin.
Hemoglobin F (HbF, fetal hemoglobin), composed of two alpha and two gamma chains, makes up about 1-2% of adult hemoglobin.

While there is only one beta globin gene (HBB), there are 2 different genes that code for alpha globin: HBA1 and HBA2. Thus, humans have 4 alpha globin gene copies (two from each parent) and 2 beta globin gene copies (one from each parent).

More than one thousand hemoglobin variants have been discovered to date. Although most do not cause disease, some variants affect the size, shape, and efficacy of red blood cells.

**Incidence and Prevalence**

Hemoglobinopathy, in all of its forms, constitutes the most common Mendelian disease in the world. Approximately 7% of the world’s population carries a mutation associated with a hemoglobinopathy. Ethnic-specific carrier rates for various hemoglobinopathies appear in the table below (adapted from March of Dimes Genetic Screening Pocket Facts). Although hemoglobinopathies are more common in certain ethnic groups, they have been described in populations worldwide.

### Ethnic-specific carrier rates for various hemoglobinopathies

**Note** *The clinically significant carrier state of alpha thalassemia is defined as the absence or dysfunction of two copies of the HBA genes. If both non-working copies are on the same chromosome, the mutations are referred to as being in ‘cis’. If there is one gene from each chromosome affected, the mutations are referred to as being in ‘trans’.*
**Symptoms**

Most cases of hemoglobinopathies in the US are diagnosed through newborn screening prior to symptom onset. The exception is the severe form of alpha thalassemia (Hb Bart syndrome), which has prenatal onset and can cause fetal or neonatal death.

Apha thalassemia: Hb Bart syndrome (absence of all 4 alpha globin genes) presents as general fetal edema, pleural and pericardial effusion, and severe anemia. HbH disease (absence of 3 of the 4 alpha globin genes) presents postnatally with anemia, enlarged spleen, and mild jaundice.

Beta thalassemia: Untreated severe beta-thalassemia (beta-thalassemia, or beta thalassemia major) can present as failure to thrive with an enlarged liver and spleen. Milder forms of the disease (Beta+ thalassemia or beta thalassemia intermedia) present later in life with milder anemia. Very mild forms of beta thalassemia can be clinically asymptomatic.

Sickle cell disease: Untreated sickle cell disease presents as hemolytic anemia, vaso-occlusive events, and swelling of the hands and feet.

Carriers of hemoglobinopathies are usually clinically asymptomatic but typically have subclinical microcytic anemia (abnormal blood indices).

**Cause**

Thalassemias are typically caused by mutations in globin chain genes that result in reduced or absent synthesis of a normal protein product. Structural hemoglobin variants are caused by mutations in globin chain genes that result in synthesis of normal quantities of an abnormal protein product.

Alpha thalassemia is caused by loss of function mutations in the HBA1 or HBA2 genes. Gene deletions are the most common causative mutations. Of non-deletion mutations, the point mutation Hb Constant Spring (HbCS) is the most common and may be clinically more severe than a deletion mutation; this mutation is most common in Southeast Asians. Symptoms occur when 3 or 4 of the 4 alpha globin genes are dysfunctional or absent. If 1 or 2 genes are dysfunctional or absent, the individual is asymptomatic and considered a carrier of alpha thalassemia.

Beta thalassemia is caused by loss of function mutations in the HBB gene. Nonsense, small frameshift, and splice site mutations are the most common causative mutations, and gene deletions are rare. In general, beta thalassemias are due to complete loss of the beta globin protein, while beta+ thalassemias are due to decreased production of beta globin.

HbS (sickle hemoglobin) is caused by a single HBB mutation (p.Glu6Val). Similarly, HbC (p.Glu6Lys) and HbE (p.Glu26Lys) are also caused by single HBB mutations. Other structural hemoglobin variants are grouped according to electrophoretic properties (HbD, HbG) but have multiple subtypes caused by different mutations, potentially in different hemoglobin chain-coding genes.
Structural hemoglobin variants can be co-inherited with one another or with alpha or beta thalassemia deletions/mutations. These combinations can result in a wide range of phenotypes, dependent upon both the specific structural variant and thalassemia mutation.\(^8\)

**Inheritance**

Most hemoglobinopathies are inherited in an autosomal recessive manner.\(^6,8\) If both parents are carriers, there is a 25% chance with each pregnancy to have an affected child.\(^4,6\)

Carriers of beta thalassemia mutations and the HbS structural variant are often referred to as having thalassemia trait or sickle cell trait. As there are 2 different alpha globin genes (HBA1 and HBA2), the absence or dysfunction of two of the four genes is required to be considered a carrier (alpha thalassemia trait). The absence or dysfunction of 1 of the 4 alpha globin genes is often referred to as silent carrier state.

**Diagnosis**

Hemoglobinopathies are diagnosed based on clinical presentation and/or hematologic laboratory analysis.\(^10\) These tests include:

- Complete blood count (CBC): mean corpuscular volume (MCV) and mean corpuscular hemoglobin (MCH) are measures of red cell size, and diagnose microcytic anemia. MCV and MCH are usually decreased in thalassemias.
- Hemoglobin electrophoresis, isoelectric focusing (IEF) and high performance liquid chromatography (HPLC) detect and quantify hemoglobin subtypes, identifying structural hemoglobin variants and detecting abnormal levels of normal adult hemoglobin.\(^1\) In beta thalassemia, HbA\(_2\) and HbF are usually increased.\(^8\)
- Exclusion of iron deficiency as a cause of anemia via serum iron concentration, ferritin, transferrin and/or total iron binding capacity assessment.

Molecular testing is not generally required for diagnosis or management purposes, but may be indicated if the hematologic results are inconclusive, when molecular findings would impact medical management, or to identify familial mutations for reproductive planning purposes.\(^6,8\)

**Treatment**

Hemoglobinopathies are treated with packed red cell transfusions as needed.\(^6,8,9\) Iron chelation therapy helps prevent iron overload in individuals receiving regular transfusions.\(^6,8\) Individuals with sickle cell disease may also be treated with hydroxyurea to increase production of fetal hemoglobin.\(^9\)
Test information

Introduction

Diagnostic testing for hemoglobinopathies is generally based on clinical findings, red blood cell indices (MCV and MCH) and results of quantitative hemoglobin electrophoresis and other protein-based analyses of hemoglobin.

HBA1 and HBA2 genetic testing

Genetic testing for hemoglobinopathies caused by variants of alpha globin genes HBA1 and HBA2 may include common mutation panel, gene sequencing, deletion/duplication analysis, or known familial mutation analysis.

HBA1 and HBA2 targeted mutation analysis

About 90% of pathogenic HBA1 and HBA2 variants can be identified by a targeted panel. Detection rates depend on ethnicity. The most common deletions are -a 3.7 , -a 4.2 , and -a 20.5 (single gene deletions), and -SEA, -MED, -FIL, and -THAI (double gene deletions). These are the deletions most commonly found in the Southeast Asian, African, Middle Eastern, West Indian, and Mediterranean populations. Some common mutation panel tests also include Hb Constant Spring.

HBA1 and HBA2 sequencing

If common deletion testing for HBA1 and HBA2 is negative or does not find the expected number of mutations, sequencing of the HBA1 and HBA2 genes can be used to identify variants caused by point mutation.

HBA1 and HBA2 deletion/duplication analysis

Fewer than 5% of pathogenic HBA1 and HBA2 variants have been detected by deletion/duplication analysis of the HBA1/HBA2 locus. Some labs perform this type of assessment instead of a targeted deletion panel. Deletion/duplication analysis is performed if a gene triplication or other copy number variation is suspected based on phenotype.

HBA1 and HBA2 known familial mutation analysis

This test looks specifically for known mutation(s) previously identified in the family. This may be accomplished through a targeted assessment of the specific familial mutation or a common deletion panel.

HBB genetic testing

Genetic testing for hemoglobinopathies caused by variants of beta globin gene HBB may include targeted mutation analysis, gene sequencing, deletion/duplication analysis, or known familial mutation analysis.
HBB targeted mutation analysis

Targeted HBB mutation panels can consist of a few of the most common structural hemoglobin variants and beta thalassemia associated mutations or dozens of reported mutations across ethnicities. Clinical sensitivity of a panel depends on patient ethnicity, hematologic test results, and the mutations included on the panel.

HBB sequencing

Full HBB gene sequencing identifies >99% of mutations in the coding region, including the common HbS and beta thalassemia mutations.

HBB deletion/duplication analysis

Beta thalassemia caused by pathogenic HBB deletion or duplication is rare, but has been reported.

HBB known familial mutation analysis

This test looks specifically for known mutation previously identified in the family. This may be accomplished through a targeted assessment of the specific familial mutation(s) or a common mutation panel.

Guidelines and evidence

Introduction

This section includes relevant guidelines and evidence pertaining to hemoglobinopathy testing.

American College of Obstetricians and Gynecologists (ACOG)

Evidence-based guidelines from ACOG (2007) recommend that couples at risk of having a child with a hemoglobinopathy be offered prenatal diagnostic options including amniocentesis or chorionic villus sampling (CVS) (level A recommendation: based on "good and consistent scientific evidence"). Identification of parental mutations should be performed before prenatal diagnosis to inform interpretation of prenatal results.

ACOG Committee Opinion 690 (2017) states that all patients considering pregnancy or already pregnant, regardless of screening strategy and ethnicity, should be offered complete blood count and screening for hemoglobinopathy.

ACOG Committee Opinion 691 (2017) expands on recommended screening methodology: All pregnant women should have a complete blood count with red cell indices. For women of high risk ethnicity (African, Mediterranean, Middle Eastern, Southeast Asian and West Indian), hemoglobin electrophoresis should also be performed. For all other women, hemoglobin electrophoresis is recommended only if red cell indices indicate low mean MCH or MCV.
The Society of Obstetricians and Gynaecologists of Canada (SOGC)

Evidence-based guidelines from SOGC (2016) state the following regarding screening for thalassemia and other hemoglobinopathies.¹⁴

- “Carrier screening for hemoglobinopathies should be offered to women/families from ethnic backgrounds with a reported increased carrier frequency, when red blood cell indices reveal a mean cellular volume < 80 fl, or electrophoresis reveals an abnormal hemoglobin type. However, the use of ethnicity alone in the carrier risk identification process may create screening inconsistency and missed opportunity for carrier identification, with both obstetrical and fetal implications. High clinical suspicion is required as well. Screening should be done in the pre-conception period or as early into the pregnancy as possible. (II-2A) (GRADE moderate/moderate)”

- “Carrier screening for thalassemia/hemoglobinopathies should be offered by the most responsible health care provider or reproductive genetic provider and include:”
  - “Complete blood count”
  - “Hemoglobin (Hb) electrophoresis (HE) or Hb high performance liquid chromatography (HHPLC)”
  - “Quantification of Hb alpha 2 and fetal Hb”
  - “Serum ferritin/H bodies (blood smear stain using brilliant cresyl blue) if microcytosis (mean cellular volume < 80 fl) and/or hypochromia (mean cellular Hb < 27 pg) in the presence of a normal HE or HHPLC assessment. (II-2A) (GRADE moderate/moderate)”

- “If the female thalassemia screening results are abnormal, a hemoglobinopathy screening protocol should be undertaken for the male partner. (III-A) (GRADE low/moderate)”

- “If both reproductive partners are found to be carriers of thalassemia or a combination of thalassemia and hemoglobin variant, they should be referred for formal genetic counselling (reproductive risks, recommended prenatal testing, and diagnostic management). (II3A) (GRADE moderate/moderate)”

British Committee for Standards in Haematology (BCSH)

The BCSH issued a comprehensive guideline for postnatal screening and diagnosis of hemoglobinopathies.¹⁵ The guideline includes indications for DNA analysis, noting that “the identification of haemoglobins is often presumptive, based on electrophoretic mobility or other characteristics in an individual of appropriate family origin. Presumptive identification should be based on a minimum of two techniques based on different principles. Definitive identification usually requires DNA analysis, mass spectrometry or protein sequencing.”

“The majority of couples at risk of having a child affected with b-thalassaemia or SCD should be identified initially by routine laboratory techniques through the antenatal
screening programme. The diagnosis of a-thalassaemia is more complicated because DNA analysis is the only accurate way to distinguish between $a^+$ and $a^0$ thalassaemia. However it is not practical to seek to confirm all potential cases of a-thalassaemia by DNA analysis because the $a^+$ form is too common and not usually clinically important."

Criteria

Introduction

Requests for hemoglobinopathy testing are reviewed using these criteria.

HBA1 and HBA2 Targeted Mutation Analysis

- Genetic Counseling:
  - Pre- and post-test genetic counseling by an appropriate provider (as deemed by the Health Plan policy), AND
- Previous Genetic Testing:
  - No previous HBA1 or HBA2 targeted mutation testing has been performed, AND
- Diagnostic Testing for Symptomatic Individuals:
  - Results of hematologic tests examining MCV, MCH, iron deficiency, and hemoglobin electrophoresis do not conclusively diagnose or rule out alpha thalassemia, and
  - Documentation from ordering provider indicates how test results will be used to directly impact medical care for the individual (e.g. change in surveillance or treatment plan), OR
- Carrier Testing:
  - Member is pregnant or of reproductive age with intention to reproduce, and
    - Both member and partner meet the following criteria:
      - MCV and/or MCH lower than reference range of testing lab, and
      - Hemoglobin electrophoresis is not consistent with beta chain abnormality, and
      - Iron deficiency anemia has been ruled out, or
  - Member is currently pregnant and meets above criteria and the father of the pregnancy is not available for testing but believed to be from a high risk ethnic population, and
  - Identification of pathogenic familial mutations is required for prenatal diagnosis or pregnancy planning, AND
• Rendering laboratory is a qualified provider of service per the Health Plan policy.

HBA1 and HBA2 Deletion Analysis

• Genetic Counseling:
  o Pre and post-test genetic counseling by an appropriate provider (as deemed by the Health Plan policy), AND

• Previous Genetic Testing:
  o Previous common mutation panel genetic testing for HBA1 or HBA2 mutations (if performed) was negative, AND

• Diagnostic Testing for Symptomatic Individuals:
  o Results of hematologic tests examining MCV, MCH, iron deficiency, and hemoglobin electrophoresis do not conclusively diagnose or rule out alpha thalassemia, and
  o Documentation from ordering provider indicates how test results will be used to directly impact medical care for the individual (e.g. change in surveillance or treatment plan), OR

• Carrier Testing:
  o Member is pregnant or of reproductive age with intention to reproduce, and
    ▪ Both member and partner meet the following criteria:
      • MCV and/or MCH lower than reference range of testing lab, and
      • Hemoglobin electrophoresis is not consistent with beta chain abnormality, and
      • Iron deficiency anemia has been ruled out, or
  o Member is currently pregnant and meets above criteria and the father of the pregnancy is not available for testing but believed to be from a high risk ethnic population, and
  o Identification of pathogenic familial mutations is required for prenatal diagnosis or pregnancy planning, AND

• Rendering laboratory is a qualified provider of service per the Health Plan policy.

HBA1 and HBA2 Sequencing

• Genetic Counseling:
  o Pre and post-test genetic counseling by an appropriate provider (as deemed by the Health Plan policy), AND
• Previous Genetic Testing
  o Previous common mutation panel or deletion/duplication genetic testing for HBA1 or HBA2 was negative, AND

• Diagnostic Testing for Symptomatic Individuals:
  o Results of hematologic tests examining MCV, MCH, iron deficiency, and hemoglobin electrophoresis do not conclusively diagnose or rule out alpha thalassemia, and
  o Documentation from ordering provider indicates how test results will be used to directly impact medical care for the individual (e.g. change in surveillance or treatment plan), OR

• Carrier Testing:
  o Member is pregnant or of reproductive age with intention to reproduce, and
    ▪ Both member and partner meet the following criteria:
      • MCV and/or MCH lower than reference range of testing lab, and
      • Hemoglobin electrophoresis is not consistent with beta chain abnormality, and
      • Iron deficiency anemia has been ruled out, or
  o Member is pregnant and meets above criteria and the father of the pregnancy is not available for testing but believed to be from a high risk ethnic population, and
  o Identification of pathogenic familial mutations is required for prenatal diagnosis or pregnancy planning, AND

• Rendering laboratory is a qualified provider of service per the Health Plan policy.

HBA1 and HBA2 Known Familial Mutation Analysis

• Genetic Counseling:
  o Pre and post-test genetic counseling by an appropriate provider (as deemed by the Health Plan policy), AND

• Previous Genetic Testing:
  o Known familial mutation in HBA1 and/or HBA2 identified in a close blood relative, and
  o No previous genetic testing for known HBA1 or HBA2 family mutation, AND

• Diagnostic Testing for Symptomatic Individuals:
o Results of hematologic tests examining MCV, MCH, iron deficiency, and hemoglobin electrophoresis do not conclusively diagnose or rule out alpha thalassemia, and

o Documentation from ordering provider indicates how test results will be used to directly impact medical care for the individual (e.g. change in surveillance or treatment plan), OR

• Carrier Screening:
  o Member is pregnant or of reproductive age with intention to reproduce, and
    ▪ Both member and partner meet the following criteria:
      • MCV and/or MCH lower than reference range of testing lab, and
      • Hemoglobin electrophoresis is not consistent with beta chain abnormality, and
      • Iron deficiency anemia has been ruled out, or
  o Member is pregnant and meets above criteria and the father of the pregnancy is not available for testing but believed to be from a high risk ethnic population, and
  o Identification of pathogenic familial mutations is required for prenatal diagnosis or pregnancy planning, OR

• Prenatal Testing:
  o Both biological parents carry HBA1/HBA2 mutations that put the pregnancy at risk for a clinically significant anemia, or
  o The pregnant member carries HBA1/HBA2 mutations that put the pregnancy at risk for a clinically significant anemia and the father of the pregnancy is unavailable but believed to be from a high risk ethnic population, AND

• Rendering laboratory is a qualified provider of service per the Health Plan policy.

**HBB Targeted Mutation Analysis**

• Genetic Counseling:
  o Pre and post-test genetic counseling by an appropriate provider (as deemed by the Health Plan policy), AND

• Previous Genetic Testing:
  o No previous genetic testing for HBB mutation, AND

• Diagnostic Testing for Symptomatic Individuals:
• Results of hematologic tests examining MCV, MCH, iron deficiency, and hemoglobin electrophoresis do not conclusively diagnose or rule out beta thalassemia, or
• Hemoglobin electrophoresis shows common structural variant caused by mutation contained on the requested panel (HbS, HbC, HbE, etc), and
• Documentation from ordering provider indicates how test results will be used to directly impact medical care for the individual (e.g. change in surveillance or treatment plan), OR

• Carrier Testing:
  • Member is pregnant or of reproductive age with intention to reproduce, and
    ▪ Both member and partner meet the following criteria:
      • MCV and/or MCH lower than reference range of testing lab, and
      • Iron deficiency anemia has been ruled out, and
      • Hemoglobin electrophoresis shows
        • elevated Hb A₂ (based on reference range of the testing lab) consistent with beta thalassemia, or
        • common structural variant caused by mutation contained on the requested panel (HbS, HbC, HbE, etc), or
  • Member is pregnant and meets above criteria and the father of the pregnancy is not available for testing but believed to be from a high risk ethnic population, and
  • Identification of pathogenic familial mutations is required for prenatal diagnosis or pregnancy planning, AND

• Rendering laboratory is a qualified provider of service per the Health Plan policy.

HBB Sequencing

• Genetic Counseling:
  • Pre and post-test genetic counseling by an appropriate provider (as deemed by the Health Plan policy), AND

• Previous Genetic Testing:
  • Previous HBB targeted mutation analysis (if performed) was negative, or
  • Individual is not of a high risk ethnicity for which HBB targeted mutation analysis is available and of high sensitivity, AND

• Diagnostic Testing for Symptomatic Individuals:
Results of hematologic tests examining MCV, MCH, iron deficiency, and hemoglobin electrophoresis do not conclusively diagnose or rule out beta thalassemia, or

Hemoglobin electrophoresis shows uncommon structural variant caused by one of several possible HBB mutations, and

Documentation from ordering provider indicates how test results will be used to directly impact medical care for the individual (e.g. change in surveillance or treatment plan), OR

• Carrier Testing:
  o Member is pregnant or of reproductive age with intention to reproduce, and
  o Both member and partner meet the following criteria:
    ▪ Results of hematologic tests examining MCV, MCH, iron deficiency, and hemoglobin electrophoresis do not conclusively rule out beta thalassemia, or
    ▪ Hemoglobin electrophoresis shows uncommon structural variant caused by one of several possible HBB mutations, or
  o The pregnant member meets above criteria for HBB carrier testing and the father of the pregnancy is unavailable but believed to be from a high risk ethnic population, and
  o Identification of pathogenic familial mutations is required for prenatal diagnosis or pregnancy planning, AND

• Rendering laboratory is a qualified provider of service per the Health Plan policy.

HBB Deletion/Duplication Analysis

• Genetic Counseling:
  o Pre- and post-test genetic counseling by an appropriate provider (as deemed by the Health Plan policy), AND

• Previous Genetic Testing:
  o Previous testing via either HBB targeted mutation analysis or HBB full sequencing performed and negative, AND

• Diagnostic Testing for Symptomatic Individuals:
  o Results of hematologic tests examining MCV, MCH, iron deficiency, and hemoglobin electrophoresis do not conclusively diagnose or rule out beta thalassemia, and
  o Documentation from ordering provider indicates how test results will be used to directly impact medical care for the individual (e.g. change in surveillance or treatment plan), OR
• Carrier Testing:
  o Member is pregnant or of reproductive age with intention to reproduce, AND
  o Both member and partner have
    ▪ Results of hematologic tests examining MCV, MCH, iron deficiency, and hemoglobin electrophoresis do not conclusively rule out beta thalassemia, or
    ▪ Hemoglobin electrophoresis shows uncommon structural variant caused by one of several possible HBB mutations, or
  o The pregnant member meets above criteria for HBB carrier testing and the father of the pregnancy is unavailable but believed to be descended from a high risk ethnic population, and
  o Identification of pathogenic familial mutations is required for prenatal diagnosis or pregnancy planning, AND

• Rendering laboratory is a qualified provider of service per the Health Plan policy

HBB Known Familial Mutation Analysis

• Genetic Counseling:
  o Pre- and post-test genetic counseling by an appropriate provider (as deemed by the Health Plan policy), AND

• Previous Genetic Testing:
  o Known familial mutation in HBB identified in a close blood relative, and
  o No previous genetic testing for known HBB family mutation, AND

• Diagnostic Testing for Symptomatic Individuals:
  o Results of hematologic tests examining MCV, MCH, iron deficiency, and hemoglobin electrophoresis do not conclusively rule out beta thalassemia, and
  o Documentation from ordering provider indicates how test results will be used to directly impact medical care for the individual (e.g. change in surveillance or treatment plan), OR

• Carrier Testing:
  o Member is pregnant or of reproductive age with intention to reproduce, AND
  o Both member and partner have
    ▪ Results of hematologic tests examining MCV, MCH, iron deficiency, and hemoglobin electrophoresis do not conclusively rule out beta thalassemia, or
    ▪ Hemoglobin electrophoresis shows uncommon structural variant caused by one of several possible HBB mutations, or
The pregnant member meets above criteria for HBB carrier testing and the father of the pregnancy is unavailable but believed to be descended from a high risk ethnic population, and

Identification of pathogenic familial mutations is required for prenatal diagnosis or pregnancy planning, AND

- Prenatal Testing
  - Both biological parents carry HBB mutations that put the pregnancy at risk for a clinically significant anemia, or
  - The pregnant member carries an HBB mutation that puts the pregnancy at risk for a clinically significant anemia and the father of the pregnancy is unavailable but believed to be from a high risk ethnic population, AND

- Rendering laboratory is a qualified provider of service per the Health Plan policy.
