Instructions for use
The following coverage policy applies to health benefit plans administered by Cigna. Coverage policies are intended to provide guidance in interpreting certain standard Cigna benefit plans and are used by medical directors and other health care professionals in making medical necessity and other coverage determinations. Please note the terms of a customer’s particular benefit plan document may differ significantly from the standard benefit plans upon which these coverage policies are based. For example, a customer’s benefit plan document may contain a specific exclusion related to a topic addressed in a coverage policy.

In the event of a conflict, a customer’s benefit plan document always supersedes the information in the coverage policy. In the absence of federal or state coverage mandates, benefits are ultimately determined by the terms of the applicable benefit plan document. Coverage determinations in each specific instance require consideration of:

1. The terms of the applicable benefit plan document in effect on the date of service
2. Any applicable laws and regulations
3. Any relevant collateral source materials including coverage policies
4. The specific facts of the particular situation

Coverage policies relate exclusively to the administration of health benefit plans. Coverage policies are not recommendations for treatment and should never be used as treatment guidelines.

This evidence-based medical coverage policy has been developed by eviCore, Inc. Some information in this coverage policy may not apply to all benefit plans administered by Cigna.

These guidelines include procedures eviCore does not review for Cigna. Please refer to the Cigna CPT code list for the current list of high-tech imaging procedures that eviCore reviews for Cigna.

CPT® (Current Procedural Terminology) is a registered trademark of the American Medical Association (AMA). CPT® five digit codes, nomenclature and other data are copyright 2017 American Medical Association. All Rights Reserved. No fee schedules, basic units, relative values or related listings are included in the CPT® book. AMA does not directly or indirectly practice medicine or dispense medical services. Neck Imaging

Neck-1: General

- A current clinical evaluation (within 60 days), which includes a relevant history and physical examination and appropriate laboratory studies and non-advanced imaging modalities, such as plain x-ray or ultrasound, are required prior to considering advanced imaging. Other meaningful contact (telephone call, electronic mail or messaging) by an established individual can substitute for a face-to-face clinical evaluation.

- Advanced imaging of the neck covers the following areas:
  - Skull base (thus a separate CPT® code for head imaging in order to visualize the skull base is not necessary).
  - Nasopharynx
  - Upper oral cavity to the head of the clavicle
  - Parotid glands and the supraclavicular region

- Ultrasound of the soft tissues of the neck including thyroid, parathyroid, parotid and other salivary glands, lymph nodes, cysts, etc. is coded as CPT® 76536. This can be helpful in more ill-defined masses or fullness and differentiating adenopathy from mass or cyst, to define further advanced imaging.

- CT Neck
  - CT Neck is usually obtained with contrast only (CPT® 70491).
    - Little significant information is added by performing a CT Neck without and with contrast (CPT® 70492), and there is the risk of added radiation exposure, especially to the thyroid.
    - CT Neck without contrast (CPT® 70490) can be difficult to interpret due to difficulty identifying the blood vessels.
    - Exception: Contrast is not generally used when evaluating the trachea with CT. Evaluate salivary duct stones in the appropriate clinical circumstance where intravenous contrast may obscure high attenuation stones.
    - Contrast enhanced CT is helpful in the assessment of cervical adenopathy and preoperative planning in the setting of thyroid carcinomas.
      - Contrast is recommended as an adjunct to US for individuals with clinical suspicion for advanced disease, including invasive primary tumor, or clinically apparent multiple or bulky lymph node involvement.
      - Contrast may cause intense and prolonged enhancement of the thyroid gland which interferes with radioactive iodine nuclear medicine studies.
      - Use of IV contrast is an important adjunct because it helps to delineate the anatomic relationship between the primary tumor and metastatic disease. Iodine is generally cleared within four to eight weeks in most individuals, so concern about iodine burden from IV contrast causing a clinically significant delay in subsequent whole-body scans (WBSs) or radioactive iodine (RAI) treatment after the imaging followed by surgery is generally unfounded. The benefit gained from improved anatomic imaging generally outweighs any potential risk of a several week delay in RAI imaging or therapy. Where there is concern, a urinary iodine to creatinine ratio can be measured.
MRI Neck

- MRI Neck is used less frequently than CT Neck.
- MRI Neck without and with contrast (CPT® 70543) is appropriate if CT suggests the need for further imaging or if ultrasound or CT suggests any of the following:
  - Neurogenic tumor (schwannoma, neurofibroma, glomus tumor, etc.)
  - Vascular malformations
  - Deep neck masses
  - Angiofibromas

See PVD-3: Cerebrovascular and Carotid Disease in Peripheral Vascular Disease Imaging Guidelines.
Neck Imaging

Neck-3.1: Dysphagia and Esophageal Disorders

➢ Gastroesophageal Reflux Disease (GERD)\(^5\)
  ➢ Non-cardiac chest pain suspected of being GERD should be evaluated first to exclude cardiac and other etiologies. See CH-4.1: Non-Cardiac Chest Pain-Imaging in the Chest Imaging Guidelines.
  ➢ Gastric emptying study (CPT® 78264) for individuals with refractory GERD symptoms, and gastroparesis is being considered.

➢ Suspected foreign body impaction and ingested foreign bodies:\(^1\)\(^-\)\(^3\)
  ➢ Plain x-rays initial imaging.
  ➢ If imaging is negative, or there is suspicion of a radiolucent foreign body (such as fish or chicken bones, wood, plastic, thin metal objects, aluminum can pop-ups, etc.):
    ▪ CT Neck and/or Chest with or without contrast.
    ▪ 3-D reconstruction (CPT® 76377) can be approved in this setting.
  ➢ The use of oral contrast is discouraged (to avoid the aspiration of contrast material) for acute dysphagia or foreign body impaction, as the contrast may not pass, may be aspirated, and can interfere with subsequent endoscopic intervention.

➢ Oropharyngeal or esophageal dysphagia\(^4\)\(^,\)\(^6\)\(^,\)\(^12\)\(^,\)\(^13\)
  ➢ Oropharyngeal (difficulty in transferring food from the mouth to the pharynx)
    ▪ Suspected neurologic causes: See appropriate sections in Head Imaging Guidelines
    ▪ Video fluoroscopic swallowing study
  ➢ Esophageal dysphagia (difficulty in transferring food down the esophagus in the retrosternal region, e.g. food sticking in the chest)
    ▪ Initial barium esophagram or upper gastrointestinal endoscopy
    ▪ Esophageal manometry if indicated
    ▪ Structural lesions identified on esophagram or endoscopy requiring further evaluation (e.g. tumors, extrinsic compression):
      ▪ CT Neck (CPT® 70491), CT Chest (CPT® 71260) and/or CT Abdomen (CPT® 74160) depending on the level of the lesion

➢ Suspected perforation, abscess, or fistula
  ➢ CT Neck, Chest, and/or Abdomen, preferably with contrast, as requested, depending on location

➢ Evaluation of structural abnormalities demonstrated on barium esophagram or endoscopy (e.g., external compression, tumor, stricture, diverticulum, etc.)
  ➢ CT Chest (CPT® 71260), CT Neck (CPT® 70491), and/or CT Abdomen (CPT® 74160) depending on location

➢ Hiatal hernia
  ➢ See AB-12.3: Hiatal Hernia in the Abdomen Imaging Guidelines

➢ Globus Sensation\(^7\)\(^-\)\(^9\)
  ➢ If alarm symptoms are present (dysphagia, weight loss, odynophagia, throat pain, hoarseness, and lateralization of symptoms)
Laryngoscopy and upper endoscopy should be performed prior to advanced imaging.
CT Neck with contrast (CPT® 70491) for ANY of the following:
- Negative or equivocal findings on laryngoscopy and upper endoscopy
- Known history of upper aerodigestive or esophageal malignancy
- Known history of lymphoma
- History of previous neck, esophageal, or gastric surgery
- Palpable abnormality on physical examination

Suspected Vascular Ring\textsuperscript{10,11,14,15}
- CTA Chest with contrast (CPT® 71275) can be used in the evaluation of suspected vascular ring
- MRI Chest without contrast, or MRI Chest without and with contrast (CPT® 71550 or CPT® 71552), can be performed if vascular ring is suspected

Background and Supporting Information
- A detailed history of the dysphagia symptoms is important to distinguish neurogenic, pharyngeal and esophageal disorders.
- Dysphagia (difficulty swallowing) can be caused by a wide range of benign and malignant causes that affects the body’s ability to move food or liquid from the mouth to the pharynx and into the esophagus.
- A short duration (weeks to months) of rapidly progressive esophageal dysphagia with associated weight loss is highly suggestive of esophageal cancer.
- Advanced imaging for individuals presenting with isolated globus rarely impacts clinical management. In a study of 148 neck CTs and 104 barium esophagrams done for the evaluation of globus sensation, there were no malignancies detected.
- Advanced imaging is generally not indicated for the evaluation of GERD, the diagnosis of which is usually made on the basis of clinical history, in conjunction with endoscopy, pH monitoring, and occasionally manometry.
- Globus sensation is a feeling of a lump or foreign body in the throat. In general, laryngoscopy, endoscopy, and physical examination will rule out malignant causes and advanced imaging is usually not needed for evaluation.

9. ACR Appropriateness Criteria Known or Suspected Congenital Heart Disease in Adults. Rev. 2016
10. ACR Appropriateness Criteria Dysphagia. Rev. 2018
Neck-4.1: Imaging

- Cervical lymphadenitis is common and follows most viral or bacterial infections of the ears, nose and throat. Painful acute lymphadenopathy should be treated with a trial of conservative therapy for 2 weeks, including antibiotics if appropriate. If there is improvement with conservative treatment, advanced imaging is not indicated but if the adenopathy persists it may be imaged as per below.\(^{1,2,4}\)

- Ultrasound (CPT® 76536) can be considered for ANY of the following:\(^{1,2,4}\)
  - Anterior neck masses\(^2\)
  - Cervical adenopathy/lymphadenitis or an inflammatory, infective, or reactive mass that has failed a 2 week trial of treatment or observation (including antibiotics if appropriate)\(^1,2\)
  - Any ill-defined mass, fullness or asymmetry\(^2\)
  - High suspicion of malignancy\(^2,4\)

- CT Neck with contrast (CPT® 70491) can be considered if:\(^{2,4}\)
  - Neck mass with high suspicion for malignancy with any ONE of the following:
    - Non-tender neck masses\(^4\)
    - Size \(\geq 1.5\) cm\(^4\)
    - Firm texture or fixation of the mass\(^4\)
    - Absence of infectious etiology\(^4\)
    - 2 or more weeks duration\(^4\)
    - Cervical adenopathy/lymphadenitis or an inflammatory, infective, or reactive mass that has failed a 2 week trial of treatment or observation (including antibiotics if appropriate)\(^2,4\)
    - Ear pain ipsilateral to the neck mass\(^4\)
    - Associated onset of persistent hoarseness, tonsil asymmetry, oral or oropharyngeal ulceration, or ulceration of skin overlying the neck mass\(^4\)
    - History of malignancy that would be primary or metastatic to the neck\(^4\)
    - Prior ultrasound results are suspicious or indeterminate for malignancy\(^2\)
  - Carcinoma found in a lymph node or other neck mass\(^2\)
  - Suspected peritonsillar, retropharyngeal or other deep neck space abscess\(^2\)
  - Suspected sarcoidosis\(^5\)
  - Preoperative evaluation of any neck mass\(^2\)

- MRI Neck without and with contrast (CPT® 70543) is supported if:\(^2\)
  - CT suggests the need for further imaging\(^2\)
  - Ultrasound or CT suggests neurogenic tumor (schwannoma, neurofibroma, glomus tumor, etc.), vascular malformations, deep neck masses, or angiofibroma.\(^2\)

Background and Supporting Information

- Painful acute lymphadenopathy associated with uncomplicated pharyngitis, URI or tonsillitis should undergo conservative therapy for two weeks including antibiotics, if appropriate. If there is improvement with conservative treatment, advanced imaging is not indicated if:\(^{3,4,5}\)
Inflammatory neck adenopathy is often associated with upper respiratory infection, pharyngitis, dental infection, HIV, and toxoplasmosis. Occasionally it is associated with sarcoidosis, and tuberculosis.

Malignancy is a greater possibility in adults that are heavy drinkers and smokers, but HPV associated disease is on the rise and there can be a high suspicion for malignancy even without these traditional risk factors.

ENT evaluation can be helpful in determining the need for advanced imaging.

Although CT and MRI can have characteristic appearances for certain entities, biopsy and histological diagnosis are the only way to obtain a definitive diagnosis. The preferred initial method of biopsy is FNA or Ultrasound guided FNA of the mass.

The most common causes of neoplastic adenopathy are metastasis from head and neck tumors and lymphoma.

Neck-7.1: Thyroid Nodule

- Serum thyrotropin (TSH) should be measured in the initial evaluation of thyroid nodule/mass/asymmetry/goiter.
- Nuclear scan (CPT® 78013 or CPT® 78014) should be performed as the initial imaging study if the serum TSH is subnormal and ANY of the following:
  - Single or multiple thyroid nodules
  - Suspicion of ectopic thyroid tissue
  - Presence of thyroid nodule in the setting of Grave’s disease (to rule out cold nodule)
  - Non-diagnostic or indeterminate FNA of thyroid nodule, (e.g. follicular lesion of undetermined significance) to see if hot (functioning) nodule that may be benign vs. cold nodule.
- Ultrasound (US) Neck (CPT® 76536) is the appropriate initial study for evaluation of suspected thyroid abnormalities, including goiter and thyroid mass(es) in the following clinical scenarios (See Neck-4.1: Imaging regarding nonthyroidal anterior neck masses):
  - Normal or High serum thyrotropin (TSH)
  - Thyroid nodule(s) being monitored with imaging: US is the indicated imaging modality rather than CT or MRI
  - Nodules ≤1 cm with very low suspicion US pattern including spongiform pattern and pure cysts do not require repeat US.
  - For more suspicious or larger nodules, if Fine Needle Aspiration (FNA) is not performed or was not diagnostic for malignancy, US can be repeated:
    - If US features are highly suspicious: repeat US every 6 months for up to 24 months.
    - If US features are of low to intermediate suspicion: repeat US at 12 and 24 months.
    - If nodule is stable after 24 months, follow-up ultrasound exams (CPT® 76536) can be performed every 3 to 5 years for interval surveillance.
- Fine-Needle Aspiration (FNA) is indicated for suspicious and/or large thyroid nodules prior to CT or MRI imaging.

* 2015 American Thyroid Management Guideline for Adult Patients with Thyroid Nodules and Differentiated Thyroid Cancer

- CT Neck with contrast (CPT® 70491) or CT Neck without contrast (CPT® 70490), or MRI Neck without and with contrast (CPT® 70543). MRI and CT are not indicated for routine thyroid nodule evaluation and should only be considered after US for:
  - Evaluation of extent of known substernal goiter
  - Airway compression
  - Presence of pathologic lymph nodes in cervical regions not visualized on ultrasound
  - Clinically suspected advanced disease confirmed by FNA, including invasive primary tumor
  - Preoperative planning for any thyroid disease

- A thyroid nodule detected for the first time during pregnancy should be managed in the same way as in non-pregnant individuals, except for avoiding the use of radioactive agents for diagnostic and therapeutic purposes

**Background and Supporting Information**

- The basis of thyroid nodule management is the use of ultrasonography (US), and/or nuclear medicine imaging, thyrotropin (TSH, formerly thyroid-stimulating hormone) assay, and FNA biopsy, together with clinical findings prior to CT or MRI imaging.

- Individual Features Suggesting Increased Risk for Thyroid Malignancy.
  - History of head and neck irradiation
  - Family history of medullary thyroid carcinoma, multiple endocrine neoplasia type 2, or papillary thyroid carcinoma
  - Age <14 or >70 years
  - Male sex
  - Growth of the nodule
Firm or hard nodule consistency
- Cervical adenopathy
- Fixed nodule
- Persistent dysphonia, dysphagia, or dyspnea

- Iodinated CT contrast may interfere with diagnostic nuclear medicine thyroid scans (scintigraphy) and radiiodine treatment.
- There is insufficient evidence supporting the use of PET to distinguish indeterminate thyroid nodules that are benign from those that are malignant.
- $^{18}$FDG-PET imaging is not routinely recommended for the evaluation of thyroid nodules with indeterminate cytology. Routine preoperative $^{18}$FDG-PET scanning is not recommended.

**Neck-7.2: This section intentionally left blank**
Neck Imaging Guidelines

Neck-7.3: Parathyroid Imaging

- Primary Hyperparathyroidism suspected
  - Parathyroid Planar Imaging (CPT® 78070), Parathyroid Planar Imaging with SPECT (CPT® 78071), Parathyroid Planar Imaging with SPECT and CT (CPT® 78072) or Ultrasound (CPT® 76536) if either:
    - Elevated serum calcium and elevated serum parathyroid hormone level.
    - Serum calcium 1 mg/dL more over lab normal value.
  - CT or MRI Neck without and with contrast (CPT® 70492 or CPT® 70543):
    - Very high calcium (≥13) suggesting parathyroid carcinoma.
    - Preoperative localization including 4D CT Neck without and with contrast (CPT® 70492 or CPT® 77293).7
    - Recurrent or persistent hyperparathyroidism following neck exploration (MRI preferred).
  - CT Chest with contrast may be indicated in rare circumstances in the evaluation of ectopic mediastinal parathyroid adenomas.6

Background and Supporting Information

- A thyroid nodule is distinct either on palpation or radiologically (incidentaloma). Nonpalpable nodules have the same risk of cancer as palpable. Nodules >1 cm are evaluated, while smaller nodules are generally evaluated if suspicious, associated with adenopathy or a history of radiation or cancer exists.

- Ultrasound is not used to screen: 1) the general population, 2) individuals with normal thyroid on palpation with a low risk of thyroid cancer, 3) individuals with hyperthyroidism, 4) individuals with hypothyroidism or 5) individuals with thyroiditis. Conversely, US can be considered in individuals who have no symptoms but are high risk as a result of: history of head and neck irradiation, total body irradiation for bone marrow transplant, exposure to fallout from radiation during childhood or adolescence, family history, thyroid cancer syndromes such as MEN2, medullary or papillary thyroid cancer, Cowden’s disease, familial adenomatous polyposis, Carney complex, Werner syndrome/progeria.

- Radionuclide thyroid scan can be considered to evaluate nodules when hyperthyroidism is present, for surveillance of thyroid cancer, or to detect non-palpable nodules. This scan is not useful for other nodules since hyper functioning nodules rarely harbor malignancy. Thyroid nodules >4 cm may be considered for thyroid lobectomy due to a high incidence of both false negative FNA biopsies and malignancy (26%).

- FNA may be repeated after an initial non-diagnostic cytology result, because repeat FNA with US guidance will yield a diagnostic cytology specimen in 75% of solid nodules and 50% of cystic nodules. However, up to 7% of nodules continue to yield non-diagnostic cytology results despite repeated biopsies and may be malignant at the time of surgery.

- Thyroid nodules may be stratified as to risk of thyroid cancer based on sonographic findings of microcalcification, hypervascularity on Doppler ultrasound, solid or cystic nature of mass and margins of mass.
Incidental focal FDG-PET uptake often corresponds to a clinically relevant thyroid nodule and ultrasound is recommended; incidentally noted diffuse thyroid FDG-PET uptake most often corresponds to inflammatory uptake, however, ultrasound should be done to ensure that there is no evidence of clinically relevant nodularity.

Elastography provides information about nodule stiffness that is complementary to gray scale ultrasound findings in nodules with indeterminate cytology or ultrasound findings. It should not be used as a substitute for gray scale ultrasound.

Use of ultrasound contrast medium is not recommended for the diagnostic evaluation of thyroid nodules and its current use is restricted to definition of size and limits of necrotic zones after minimally invasive nodule ablation techniques.

# Neck-8: Trachea and Bronchus

## Neck-8.1: Imaging

| 25 |  |
Neck Imaging Guidelines

Neck-8.1: Imaging

- Plain x-rays neck and chest and bronchoscopy are the initial imaging studies for evaluating individuals with suspected tracheal and visualized bronchial pathology. Bronchoscopy can further evaluate the distal (endo) bronchial tree.
  - Suspected tracheal disease can be identified by inspiratory stridor and a characteristic flow-volume loop of PFTs.\(^1\)

- CT Neck with contrast (CPT® 70491) or without contrast (CPT® 70490) and/or CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250) can be performed to further evaluate abnormalities, which include tracheal or bronchial tumor, foreign bodies, or persistent segmental or lobar lung collapse seen on other imaging studies.\(^1,2\)

- Expiratory HRCT (CPT® 71250) is indicated in individuals with obstructive physiology tracheomalacia.\(^1\)

- Trachea or bronchial “inspissation” without an abnormality described above, is not a risk for malignancy.\(^3\)
