Instructions for use

The following coverage policy applies to health benefit plans administered by Cigna. Coverage policies are intended to provide guidance in interpreting certain standard Cigna benefit plans and are used by medical directors and other health care professionals in making medical necessity and other coverage determinations. Please note the terms of a customer’s particular benefit plan document may differ significantly from the standard benefit plans upon which these coverage policies are based. For example, a customer’s benefit plan document may contain a specific exclusion related to a topic addressed in a coverage policy.

In the event of a conflict, a customer’s benefit plan document always supersedes the information in the coverage policy. In the absence of federal or state coverage mandates, benefits are ultimately determined by the terms of the applicable benefit plan document. Coverage determinations in each specific instance require consideration of:

1. The terms of the applicable benefit plan document in effect on the date of service
2. Any applicable laws and regulations
3. Any relevant collateral source materials including coverage policies
4. The specific facts of the particular situation

Coverage policies relate exclusively to the administration of health benefit plans. Coverage policies are not recommendations for treatment and should never be used as treatment guidelines.

This evidence-based medical coverage policy has been developed by eviCore, Inc. Some information in this coverage policy may not apply to all benefit plans administered by Cigna.

These guidelines include procedures eviCore does not review for Cigna. Please refer to the Cigna CPT code list for the current list of high-tech imaging procedures that eviCore reviews for Cigna.

CPT® (Current Procedural Terminology) is a registered trademark of the American Medical Association (AMA). CPT® five digit codes, nomenclature and other data are copyright 2017 American Medical Association. All Rights Reserved. No fee schedules, basic units, relative values or related listings are included in the CPT® book. AMA does not directly or indirectly practice medicine or dispense medical services. PEDCH-1.1: Pediatric Chest Imaging Age Considerations

Many conditions affecting the chest in the pediatric population are different diagnoses than those occurring in the adult population. For those diseases which occur in both pediatric and adult populations, differences may exist in management due to individual age, comorbidities, and differences in disease natural history between children and adults.

- Individuals who are <18 years old should be imaged according to the Pediatric Chest Imaging Guidelines, and individuals who are ≥18 years old should be imaged according to the Adult Chest Imaging Guidelines, except where directed otherwise by a specific guideline section.

PEDCH-1.2: Pediatric Chest Imaging Appropriate Clinical Evaluation

- A recent (within 60 days) face to face evaluation including a detailed history, physical examination, and appropriate laboratory studies should be performed prior to considering advanced imaging (CT, MRI, Nuclear Medicine), unless the individual is undergoing guideline-supported scheduled follow-up imaging evaluation.

- Unless otherwise stated in a specific guideline section, the use of advanced imaging to screen asymptomatic individuals for disorders involving the chest is not supported. Advanced imaging of the chest should only be approved in individuals who have documented active clinical signs or symptoms of disease involving the chest.

- Unless otherwise stated in a specific guideline section, repeat imaging studies of the chest are not necessary unless there is evidence for progression of disease, new onset of disease, and/or documentation of how repeat imaging will affect individual management or treatment decisions.

PEDCH-1.3: Pediatric Chest Imaging Modality General Considerations

- MRI
  - MRI Chest is generally performed without and with contrast (CPT® 71552) unless the individual has a documented contraindication to gadolinium or otherwise stated in a specific guideline section.
  - Due to the length of time required for MRI acquisition and the need to minimize individual movement, anesthesia is usually required for almost all infants (except neonate) and young children (age <7 years), as well as older children with delays in development or maturity. This anesthesia may be administered via oral or intravenous routes. In this individual population, MRI sessions should be planned with a goal of minimizing anesthesia exposure by adhering to the following considerations:
    - MRI procedures can be performed without and/or with contrast use as supported by these condition-based guidelines. If intravenous access will already be present for anesthesia administration and there is no contraindication for using contrast, imaging without and with contrast may be appropriate if requested. By doing so, the requesting provider may avoid
repetitive anesthesia administration to perform an MRI with contrast if the initial study without contrast is inconclusive.

- Recent evidence-based literature demonstrates the potential for gadolinium deposition in various organs including the brain, after the use of MRI contrast.
- The U.S. Food and Drug Administration (FDA) has noted that there is currently no evidence to suggest that gadolinium retention in the brain is harmful and restricting gadolinium-based contrast agents (GBCAs) use is not warranted at this time. It has been recommended that GBCA use should be limited to circumstances in which additional information provided by the contrast agent is necessary and the necessity of repetitive MRIs with GBCAs should be assessed.

- If multiple body areas are supported by eviCore guidelines for the clinical condition being evaluated, MRI of all necessary body areas should be obtained concurrently.
- The presence of surgical hardware or implanted devices may preclude MRI.
- The selection of best examination may require coordination between the provider and the imaging service.

CT
- CT Chest is generally performed either with contrast (CPT® 71260) or without contrast (CPT® 71250).
  - There are no generally accepted pediatric indications for CT Chest without and with contrast (CPT® 71270).
- CT should not be used to replace MRI in an attempt to avoid sedation unless listed as a recommended study in a specific guideline section.
- The selection of best examination may require coordination between the provider and the imaging service.

Ultrasound
- Ultrasound chest (CPT® 76604) or axilla (CPT® 76882) is indicated as an initial study for evaluating adenopathy, palpable chest wall lesions, pleural effusion or thickening, patency of thoracic vasculature, and diaphragm motion abnormalities.
- For those individuals who do require advanced imaging, ultrasound can be very beneficial in selecting the proper modality, body area, image sequences, and contrast level that will provide the most definitive information for the individual.

The guidelines listed in this section for certain specific indications are not intended to be all-inclusive; clinical judgment remains paramount and variance from these guidelines may be appropriate and warranted for specific clinical situations.

PEDCH-2: Lymphadenopathy

- Axillary lymphadenopathy imaging indications in pediatric individuals are identical to those for adult individuals. See CH-2.2: Axillary Lymphadenopathy (and Mass) in the Chest Imaging Guidelines.

- Supraclavicular adenopathy in pediatric individuals is almost always pathologic, and advanced imaging is indicated prior to excisional biopsy. Fine needle aspiration, while common in adults prior to advanced imaging, is inappropriate for evaluating lymphadenopathy in pediatric individuals. ANY of the following studies for evaluation of supraclavicular adenopathy in children:
  - CT Chest with contrast (CPT® 71260).
  - MRI Chest without and with contrast (CPT® 71552).
  - Ultrasound Chest (CPT® 76604).

- If malignancy is suspected, see the appropriate imaging guidelines as below:
  - Soft tissue sarcoma: PEDONC-8: Pediatric Soft Tissue Sarcomas in the Pediatric Oncology Imaging Guidelines.

Reference
The causes of mediastinal masses in children are generally different than those in adults, and the imaging considerations are different.

- Chest x-ray is indicated as an initial study for all individuals with suspected mediastinal mass.
- CT Chest with contrast (CPT® 71260) is indicated for any pediatric individual with a mediastinal mass identified on Chest x-ray.
  - Masses can be very large and anterior masses frequently cause compression of the trachea and/or mediastinal blood vessels.
- MRI Chest without and with contrast (CPT® 71552) is indicated for any pediatric individual with:
  - A posterior (paravertebral) mediastinal mass on CT Chest that invades the spinal canal.
  - CT findings are inconclusive regarding specific anatomy.
  - MRI should not be used for individuals with large anterior mediastinal masses if anesthesia is necessary to complete the study.
- PET/CT (CPT® 78815) is indicated prior to biopsy in pediatric individuals if lymphoma is known or strongly suspected or there is evidence of tracheal compression on CT imaging. See PEDONC-5: Pediatric Lymphoma in the Pediatric Oncology Imaging Guidelines.
- MIBG (CPT® 78804) is indicated and can be approved prior to biopsy in pediatric individuals if neuroblastoma is known or strongly suspected. See PEDONC-6: Neuroblastoma in the Pediatric Oncology Imaging Guidelines.
- Ultrasound (CPT® 76604) can be approved in children younger than 5 years old to distinguish prominent but otherwise normal thymus from true mediastinal mass.
- A single repeat CT Chest with contrast (CPT® 71260) can be approved to confirm stability and avoid biopsy for individuals with NONE of the following features:
  - Anterior mediastinal mass.
  - Enlarged lymph nodes anywhere in the imaging field.
  - Lymphopenia.
  - Pleural effusion.

References
PEDCH-4: Hemoptysis

PEDCH-4.1: Imaging
PEDCH-4.1: Imaging

- True hemoptysis is rare in pediatric individuals, and a face-to-face evaluation including detailed history, physical examination, and appropriate laboratory studies should be performed prior to considering advanced imaging.
  - Aspirated blood from epistaxis or emesis frequently presents as hemoptysis, and history and physical examination will aid in this assessment.

- Chest x-ray is indicated as an initial study for stable individuals.
  - Advanced imaging is not indicated for individuals with epistaxis and a normal chest radiograph and no personal or family history of underlying lung disease or bleeding disorder.
  - CT Chest with contrast (CPT® 71260) is indicated for all other pediatric individuals with hemoptysis.
    - CT Chest without contrast (CPT® 71250) for individuals with a documented allergy to CT contrast or significant renal dysfunction.

- MRI is not indicated in the evaluation of pediatric hemoptysis.

References
PEDCH-5: Cystic Fibrosis and Bronchiectasis

PEDCH-5.1: Cystic Fibrosis

PEDCH-5.2: Bronchiectasis Not Associated with Cystic Fibrosis
PEDCH-5.1: Cystic Fibrosis

- Chest x-ray is the primary study for initial evaluation of acute clinical symptoms in individuals with cystic fibrosis.
- CT Chest without contrast (CPT® 71250) or with contrast (CPT® 71260) is indicated for the following (without initial Chest x-ray):
  - Hemoptysis.
  - Pneumonia worsening despite antibiotic therapy.
  - Pleural effusion or empyema.
  - Suspected fungal pneumonia.
  - Monitoring treatment changes on bronchiectasis.
  - Expiratory CT for evaluating small airways disease.
  - Pre- and post-lung transplant evaluation.
- Low dose CT Chest without contrast (CPT® 71250) is indicated every 2 years for monitoring of bronchiectasis and small airways disease.

PEDCH-5.2: Bronchiectasis Not Associated with Cystic Fibrosis

- Bronchiectasis not associated with cystic fibrosis is rare in pediatric individuals, and imaging indications are identical to those for adult individuals. See CH-7: Bronchiectasis in the Chest Imaging Guidelines.

References
Bronchiolitis is a self-limiting viral infection causing inflammation of the small airways, most common in infants under 12 months of age.

- Chest x-rays are indicated when there is a clinical suspicion of pneumonia or other complications.

- Advanced imaging is not indicated for routine evaluation or monitoring of bronchiolitis, but CT Chest with contrast (CPT® 71260) can be approved for the following:
  - Pleural effusion or empyema on recent Chest x-ray.
  - Immunocompromised individual with acute pulmonary symptoms.
  - Abnormality on recent Chest x-ray suggesting condition other than bronchiolitis.

References
PEDCH-7: Pneumonia

- Pneumonia imaging indications in pediatric individuals are very similar to those for adult individuals. See CH-13: Pneumonia in the Chest Imaging Guidelines.

- Pediatric-specific imaging considerations include the following:
  - CT Chest with contrast (CPT® 71260) for immunocompromised individuals with acute pulmonary symptoms.
  - CT Chest without contrast (CPT® 71250) or with contrast (CPT® 71260) for individuals with recurrent lower respiratory tract infections.
  - Ultrasound chest (CPT® 76604) for evaluation of complicated or recurrent childhood pneumonia.

References
PEDCH-8: Solitary Pulmonary Nodule

The Fleischner Society guidelines for solitary pulmonary nodule management do not apply to pediatric individuals. An incidental solitary pulmonary nodule in a child representing a primary lung carcinoma has never been reported in the literature. Similarly, an extrathoracic malignancy presenting with an incidental solitary pulmonary nodule in an otherwise healthy child is very rare.

- CT Chest with contrast (CPT® 71260) as a one-time evaluation for all children with a pulmonary nodule incidentally discovered on other imaging.

- Follow up imaging of incidental solitary pulmonary nodules in asymptomatic healthy children is not necessary.
  - Follow up imaging is indicated for the following:
    - Immune compromised individuals.
    - Malignancy (see below).
    - Invasive infection.
    - New or worsening pulmonary symptoms.

- Children with a malignant solid tumor who have pulmonary nodules of any size should have imaging according to the guideline section for the specific cancer type. See Pediatric Oncology Imaging Guidelines for specific imaging indications.

- This guideline section does not apply to multiple pulmonary nodules, which are imaged according to the underlying disorder in pediatric individuals.

Background and Supporting Information

A nodule is any pulmonary or pleural lesion that is a discrete, spherical opacity 2-30 mm in diameter surrounded by normal lung tissue. A larger nodule is called a mass. Entities that are not nodules, and are considered benign, include non-spherical linear, sheet-like, two-dimensional or scarring opacities.

References

PEDCH-9: Positive PPD or Tuberculosis

Positive PPD and tuberculosis imaging indications in pediatric individuals are similar to those for adult individuals. See CH-14.1: PPD or TB (Mycobacterium tuberculosis and Mycobacterium avium complex (MAC)) in the Chest Imaging Guidelines.

Pediatric-specific imaging considerations include the following:
- MRI Spine with and without contrast can be approved at symptomatic levels in individuals with concern for spinal involvement of tuberculosis.

References
PEDCH-10: Asthma

- Chest x-ray is indicated when the individual’s condition does not respond to standard therapy, to identify complications, such as pneumonia or to rule out other causes of respiratory distress.

- Advanced imaging is not indicated for routine evaluation or monitoring of asthma, but CT Chest without (CPT® 71250) or with (CPT® 71260) contrast can be approved for the following:
  - Pleural effusion or empyema on recent Chest x-ray.
  - Immunocompromised individual with acute pulmonary symptoms.
  - Abnormality on recent Chest x-ray suggesting condition other than asthma, including suspected foreign body.
  - Asthma and poor response to bronchodilators or conventional inhaled corticosteroid therapy in whom associated conditions, such as allergic bronchopulmonary aspergillosis and eosinophilic pneumonia can mimic asthma.

References

CT Chest without contrast (CPT® 71250), MRI Chest with and without contrast (CPT® 71552) or MRI Chest without contrast (CPT® 71550) is indicated in individuals with a pectus deformity for:

- Preoperative planning.
- Significant cardiac displacement after Chest x-ray and echocardiography (CPT® 93306).
- Evidence of pulmonary impingement after Chest x-ray and pulmonary function tests (PFTs) if there is increasing shortness of breath. **Note:** It may not be possible to obtain PFTs in children younger than 9 years old.
- Evaluation of congenital heart disease or Marfan’s syndrome when suspected in those individuals with pectus deformities.

Pediatric Chest Imaging

**PEDCH-13.1: Vascular Ring**

- Chest x-ray is the recommended initial study in individuals with respiratory symptoms.
- Barium esophagram is the recommended initial study in individuals with feeding difficulties.
- CT Chest with contrast (CPT® 71260), CTA Chest (CPT® 71275) or MRA Chest (CPT® 71555) in individuals with known or suspected vascular ring after Chest x-ray or barium esophagram.
- Echocardiogram can be approved to rule out associated congenital heart disease.
  - CPT® 93303, CPT® 93306, CPT® 93320, and CPT® 93325 can be approved for initial evaluation of individuals with vascular ring and no prior echocardiograms.

**Background and Supporting Information**

Vascular rings generally present with either respiratory symptoms (stridor, wheezing, tachypnea, cough) or feeding difficulties (dysphagia, slow feeding, hyperextension of the head while feeding, weight loss, failure to thrive) but can also be discovered incidentally on imaging obtained for other purposes.

**PEDCH-13.2: Other Vascular Malformations**

See **PEDCH-14.2: Pulmonary Arteriovenous Malformations** for Pulmonary AVMs.

See **PEDPVD-2: Vascular Anomalies** in the Pediatric Peripheral Vascular Disease Imaging Guidelines.

</table>
**PEDCH-14.1: Congenital Cystic Lung Diseases**

- This section includes common congenital cystic lung lesions such as:
  - Bronchogenic cyst
  - Congenital pulmonary airway malformation (congenital cystic adenomatoid malformation)
  - Congenital lobar overinflation

- Cystic Lung disease may be first identified on prenatal ultrasound, or discovered incidentally on Chest x-ray.

- Chest x-ray is indicated before considering advanced imaging.

- CT Chest with contrast (CPT® 72160) may be approved when Chest x-ray suggests a cystic lung lesion.

- MRI Chest with and without contrast (CPT® 71552) can be approved if CT is inconclusive or if requested for pre-operative planning

**PEDCH-14.2: Pulmonary Arteriovenous Malformations**

- Pulmonary arteriovenous malformations (PAVMs) are vascular structures that most commonly result from abnormal communication between pulmonary arteries and pulmonary veins.
  - Chest x-ray are indicated as an initial imaging modality for individuals with known AVMs, or individuals presenting with hypoxemia and/or hemoptysis
  - CTA or MRA may be approved in individuals with known AVM or abnormal Chest x-ray suggesting AVM for treatment planning
