Instructions for use
The following coverage policy applies to health benefit plans administered by Cigna. Coverage policies are intended to provide guidance in interpreting certain standard Cigna benefit plans and are used by medical directors and other health care professionals in making medical necessity and other coverage determinations. Please note the terms of a customer’s particular benefit plan document may differ significantly from the standard benefit plans upon which these coverage policies are based. For example, a customer’s benefit plan document may contain a specific exclusion related to a topic addressed in a coverage policy.

In the event of a conflict, a customer’s benefit plan document always supersedes the information in the coverage policy. In the absence of federal or state coverage mandates, benefits are ultimately determined by the terms of the applicable benefit plan document. Coverage determinations in each specific instance require consideration of:

1. The terms of the applicable benefit plan document in effect on the date of service
2. Any applicable laws and regulations
3. Any relevant collateral source materials including coverage policies
4. The specific facts of the particular situation

Coverage policies relate exclusively to the administration of health benefit plans. Coverage policies are not recommendations for treatment and should never be used as treatment guidelines.

This evidence-based medical coverage policy has been developed by eviCore, Inc. Some information in this coverage policy may not apply to all benefit plans administered by Cigna.

These guidelines include procedures eviCore does not review for Cigna. Please refer to the Cigna CPT code list for the current list of high-tech imaging procedures that eviCore reviews for Cigna.

CPT® (Current Procedural Terminology) is a registered trademark of the American Medical Association (AMA). **PEDPVD-1.1: Age Considerations**
Many conditions affecting the peripheral vascular system in the pediatric population are different diagnoses than those occurring in the adult population. For those diseases which occur in both pediatric and adult populations, minor differences may exist in management due to individual age, comorbidities, and differences in disease natural history between children and adults.

- Individuals who are < 18 years old should be imaged according to the Pediatric peripheral vascular disease imaging guidelines, and individuals who are ≥ 18 years old should be imaged according to the Adult peripheral vascular disease imaging guidelines, except where directed otherwise by a specific guideline section.

**PEDPVD-1.2: Imaging Appropriate Clinical Evaluation**

- A recent (within 60 days) face to face evaluation including a detailed history, physical examination, and appropriate laboratory studies should be performed prior to considering advanced imaging (CT, MR, Nuclear Medicine), unless the individual is undergoing guideline-supported scheduled follow up imaging evaluation.

- Unless otherwise stated in a specific guideline section, the use of advanced imaging to screen asymptomatic individuals for disorders involving the peripheral vascular system is not supported. Advanced imaging of the peripheral vascular system should only be approved in individuals who have documented active clinical signs or symptoms of disease involving the peripheral vascular system.

- Unless otherwise stated in a specific guideline section, repeat imaging studies of the peripheral vascular system are not necessary unless there is evidence for progression of disease, new onset of disease, and/or documentation of how repeat imaging will affect individual management or treatment decisions.

**PEDPVD-1.3: Modality General Considerations**

- MRI

  - MRI is generally performed without and with contrast unless the individual has a documented contraindication to gadolinium or otherwise stated in a specific guideline section.
  
  - Due to the length of time for image acquisition and the need for, the individual to lie still, anesthesia is required for almost all infants and young children (age < 7 years), as well as older children with delays in development or maturity. In this individual population, MRI imaging sessions should be planned with a goal of minimizing anesthesia exposure adhering to the following considerations:

    - MRI should always be performed without and with contrast unless there is a specific contraindication to gadolinium use since the individual already has intravenous access for anesthesia.
    - Recent evidence based literature demonstrates the potential for gadolinium deposition in various organs including the brain after the use of MRI contrast.
The U.S. Food and Drug Administration (FDA) has noted that there is currently no evidence to suggest that gadolinium retention in the brain is harmful and restricting gadolinium-based contrast agents (GBCAs) use is not warranted at this time. It has been recommended that GBCA use should be limited to circumstances in which additional information provided by the contrast agent is necessary and the necessity of repetitive MRIs with GBCAs should be assessed.

- If requesting clinicians indicate that a non-contrast study is being requested with specific concern for gadolinium retention, the exam can be approved.
- If multiple body areas are supported by eviCore guidelines for the clinical condition being evaluated, MRI of all necessary body areas should be obtained concurrently in the same anesthesia session.
- The presence of surgical hardware or implanted devices may preclude MRI.
- The selection of best examination may require coordination between the provider and the imaging service.

CT
- CT or CTA may be appropriate for further evaluation of abnormalities suggested on prior US or MRI Procedures.
- CT may be appropriate without prior MR or US, especially in the following (non-exhaustive list of) settings:
  - Lymphatic malformations
  - Vascular abnormalities including vasculitis, thrombosis, narrowing, aneurysm, dissection, and varices.
  - For preoperative planning or assessment of post-operative complications.
- In some cases, especially in follow-up of a known finding, it may be appropriate to limit the exam to the region of concern to reduce radiation exposure.
- CT should not be used to replace MRI in an attempt to avoid sedation unless listed as a recommended study in a specific guideline section.
- The selection of best examination may require coordination between the provider and the imaging service.

Ultrasound
- Ultrasound can be helpful in evaluating arterial, venous, and lymphatic malformations.
- Ultrasound can be limited by the imaging window and the individual body type.
- CPT® codes vary by body area and presence or absence of Doppler imaging and are included in the table at the beginning of this guideline.
- The guidelines listed in this section for certain specific indications are not intended to be all-inclusive; clinical judgment remains paramount and variance from these guidelines may be appropriate and warranted for specific clinical situations.

PEDPVD-2.1: General Information

- Individuals with aggressive lesions being treated with systemic therapy can have imaging approved for treatment response every 3 months during active treatment.
- Annual surveillance imaging of known vascular or lymphatic malformations can be approved for body areas where growth could cause significant organ dysfunction or functional impairment.

Background and Supporting Information

Vascular and lymphatic malformations encompass a broad variety of conditions, and have very heterogeneous natural history and treatment approaches. Lesions can be divided into low flow lesions (lymphatic, capillary and venous malformations), and high flow lesions (arteriovenous malformations and fistulas).

PEDPVD-2.2: Lymphatic Malformations

- Ultrasound is indicated as an initial examination for superficial lesions.
  - Large lesion characterization may be limited by ultrasound imaging window.
  - Ultrasound is also limited in evaluating malformation relationship to airway or bony structures.
- MRI without contrast or without and with contrast of the affected body part is indicated for:
  - Lymphatic malformations involving deep tissues
  - Malformations too large to be completely imaged with ultrasound
  - Inconclusive ultrasound findings
  - Preoperative planning
- CT is of limited value in evaluating lymphatic malformations
  - CT with contrast of the affected body part for lesions with acute enlargement and concerns for compression when MRI is contraindicated.

Background and Supporting Information

Lymphatic malformations are composed of dilated lymphatic channels filled with proteinaceous fluid and do not connect to normal lymphatic channels. They are typically soft, non-pulsatile masses with normal overlying skin.

PEDPVD-2.3: Venous Malformations

- Ultrasound with Doppler is indicated as an initial examination for superficial lesions.
  - Large lesion characterization may be limited by ultrasound imaging window.
  - Ultrasound is also limited in evaluating malformation relationship to airway or bony structures.
- MRI without contrast or without and with contrast of the affected body part can be approved for venous malformations for preoperative assessment to evaluate the extent of malformation and their relationship to normal structures.
MRA or CTA have a limited role in evaluating most venous malformations, but may be indicated (contrast as requested of the affected body part) if MRI or CT are equivocal and the results will impact acute management decisions.

CT can also be used to characterize venous malformations and their relationship to normal structures, but is generally not as accurate as MRI.

- CT with contrast of the affected body part when MRI is inconclusive or contraindicated

**Background and Supporting Information**

Venous malformations are slow-flow lesions characterized by dilated venous spaces and a normal arterial component. They are soft, compressible, non-pulsatile lesions that are usually blue to deep purple in color. Lesions can range from very small to large infiltrating ones. Some may change size with Valsalva.

Venous malformations are usually isolated, but they may be seen in multiple syndromes including Klippel-Trenaunay (KT) syndrome, Blue Rubber Bleb Nevus syndrome (BRBN), Maffucci syndrome, Proteus syndrome, Bannayan-Riley-Ruvalcaba syndrome, Parkes-Weber syndrome and congenital lipomatous overgrowth, vascular malformations, epidermal nevi and scoliosis/skeletal/spinal anomalies (CLOVES) syndrome.

**PEDPVD-2.4: Capillary Malformations**

- MRI is indicated to evaluate occult underlying neurologic structures

**Background and Supporting Information**

Capillary Malformations are associated with encephalocele, spinal dysraphism, or Sturge-Weber syndrome.

Capillary malformations, also known as port wine stains, are characterized by a collection of small vascular channels in the dermis and generally do not require imaging because the diagnosis is made clinically.

**PEDPVD-2.5: Arteriovenous Malformations (AVMs) and Fistulas**

- Ultrasound with Doppler is indicated as an initial examination for superficial lesions.
  - Large lesion characterization may be limited by ultrasound imaging window.
  - Ultrasound is also limited in evaluating AVM relationship to airway or bony structures.

- MRI without contrast or without and with contrast of the affected body part is also indicated for evaluation of AVMs, and is useful in evaluating the extent of AVMs and their relationship to normal structures.

- MRA (contrast as requested) of the affected body part for evaluation and surveillance of known AVMs.
- It is unusual for both MRI and MRA to be necessary for routine treatment response or surveillance imaging of AVMs, but both may be indicated for preoperative planning.

- CT and CTA can also be used to characterize AVMs and their relationship to normal structures, but is generally not better than MRI and has associated radiation risks.
  - CT with contrast and/or CTA (contrast as requested) of the affected body part when MRI and/or MRA is inconclusive or contraindicated.

**Background and Supporting Information**

Arteriovenous malformations are characterized by a network of multiple abnormal vascular channels interposed between enlarged feeding arteries and draining veins. The arteriovenous fistula has a single communication interposed between a feeding artery and a draining vein. The normal capillary bed is absent in both lesions. Both lesions may have an aggressive clinical course and are characterized by a reddish pulsatile mass which has a thrill or bruit. Though often recognized at birth, these lesions may grow and present near adolescence.

**PEDPVD-2.6: Vascular Tumors**

- Ultrasound with Doppler is indicated as an initial examination for vascular tumors.
  - Large lesion characterization may be limited by ultrasound imaging window.
  - Ultrasound is also limited in evaluating malformation relationship to airway or bony structures.

- MRI without contrast or without and with contrast of the affected body part is also indicated for evaluation of vascular tumors, and is useful in evaluating the extent of arteriovenous malformations and their relationship to normal structures, as well as response to therapy.

- MRA (contrast as requested) of the affected body part for evaluation and surveillance of known vascular tumors.

- It is unusual for both MRI and MRA to be necessary for routine treatment response or surveillance imaging of vascular tumors, but both may be indicated for preoperative planning.

- CT and CTA can also be used to characterize vascular tumors and their relationship to normal structures, but is generally not better than MRI and has associated radiation risks.
  - CT with contrast and/or CTA (contrast as requested) of the affected body part when MRI and/or MRA is inconclusive or contraindicated.

**Background and Supporting Information**

Vascular tumors include a variety of benign, borderline, and malignant tumors, which have variable clinical courses, including Epithelioid hemangioma, Kaposiform hemangioendothelioma, Kaposi sarcoma, Epithelioid hemangioendothelioma and Angiosarcoma of soft tissue.

PEDPVD-3: Vasculitis

| PEDPVD-3.1: General Information | 14 |
| PEDPVD-3.2: Large Vessel Vasculitis | 14 |
| PEDPVD-3.3: Medium Vessel Vasculitis | 14 |
| PEDPVD-3.4: Small Vessel Vasculitis | 15 |
**PEDPVD-3.1: General Information**

Systemic vasculitis is much less common in children than in adults, although the diagnostic pathways and treatment options are similar.

- PET/CT is considered investigational for management of pediatric vasculitis at this time.
  - There are limited data suggesting PET may have similar accuracy to MRA in the initial diagnosis of Takayasu arteritis, but is not helpful in assessing treatment response and has not been shown to improve individual outcomes to date.

**PEDPVD-3.2: Large Vessel Vasculitis**

- ANY of the following are indicated for evaluation of Takayasu arteritis:
  - MRA of the affected body area(s) (contrast as requested)
  - CTA of the affected body area(s) (contrast as requested)
  - Ultrasound with Doppler of the affected body area(s)
  - Individuals with aggressive disease being treated with systemic therapy can have imaging (see specific sections for details regarding modality and contrast level) for treatment response every 3 months during active treatment.

- Annual surveillance imaging of known involved body areas to detect progressive vascular damage that may require intervention.

*Background and Supporting Information*

Takayasu arteritis is the predominant large vessel vasculitis occurring in children.

**PEDPVD-3.3: Medium Vessel Vasculitis**

- ANY of the following are indicated for evaluation of polyarteritis nodosa:
  - MRA of the affected body area(s) (contrast as requested)
  - CTA of the affected body area(s) (contrast as requested)
  - Ultrasound with Doppler of the affected body area(s)

- Individuals with aggressive disease being treated with systemic therapy can have imaging (see specific sections for details regarding modality and contrast level) for treatment response every 3 months during active treatment.

- Annual surveillance imaging of known involved body areas to detect progressive vascular damage that may require intervention.

*Background and Supporting Information*

Polyarteritis nodosa and Kawasaki Disease are the primary medium vessel vasculitides occurring in children. See [PEDCD-6: Kawasaki Disease](#) for imaging guidelines for that disease.
**PEDPVD-3.4: Small Vessel Vasculitis**

- Advanced imaging is not sensitive enough to detect changes in small vessels, and is not indicated for primary assessment of any small vessel vasculitis.

- End-organ damage occurs with several of the small vessel vasculitides, and the following advanced imaging is indicated:
  - Granulomatosis with polyangitis (GPA, formerly known as Wegener’s granulomatosis)
    - CT Sinuses (CPT® 70486)
    - CT Chest without contrast (CPT® 71250) or with contrast (CPT® 71260)
  - Eosinophilic granulomatosis with polyangitis (EGPA, formerly known as Churg-Strauss Syndrome)
    - CT Chest without contrast (CPT® 71250) or with contrast (CPT® 71260)
  - Immune complex associated small-vessel vasculitis [immunoglobulin A–associated vasculitis (IgAV)]
    - Doppler ultrasound of the affected body part (most commonly abdomen)

- These imaging studies are indicated in the following circumstances:
  - New or worsening clinical symptoms affecting the body area requested.
  - Assessment of response to medical therapy when a change in treatment regimen is being considered.
  - Annual imaging to evaluate extent of disease.

<td>17</td>
</tr>
<tr>
<td>PEDPVD-4.3: Visceral Artery Aneurysms</td>
<td>17</td>
</tr>
</tbody>
</table>
**PEDPVD-4.1: Thoracic Aortic Disease**

- MRA (CPT® 71555) or CTA (CPT® 71275) Chest can be used for screening and follow-up of thoracic aortic abnormalities in individuals with Loeys-Dietz syndrome, Marfan syndrome, coarctation of the aorta, Takayasu arteritis, neurofibromatosis, William syndrome, Ehler Danlos syndrome, congenital rubella syndrome, or Kawasaki syndrome.

- Screening MRAs (preferred) or CTAs from the head through the pelvis may be performed one time in individuals diagnosed with Loeys-Dietz syndrome. Follow-up imaging of discovered aneurysms may be appropriate no more frequently than annually as requested by a specialist.

**PEDPVD-4.2: Aortic Congenital Vascular Malformations**

- Cardiac MRI without contrast (CPT® 75557) or without and with contrast (CPT® 75561), MRA Chest (CPT® 71555), CT Chest with contrast (CPT® 71260), or CTA Chest (CPT® 71275) may be indicated for evaluation.

- Vascular rings may impact both the esophagus and trachea. See PEDNECK-7: *Esophagus* and/or PEDNECK-8: *Trachea* for additional guidelines.

**PEDPVD-4.3: Visceral Artery Aneurysms**

- Visceral artery imaging indications in pediatric individuals are identical to those for adult individuals. See PVD-6: *Aortic Disorders, Renal Vascular Disorders and Visceral Artery Aneurysms* for imaging guidelines.
