Instructions for use

The following coverage policy applies to health benefit plans administered by Cigna. Coverage policies are intended to provide guidance in interpreting certain standard Cigna benefit plans and are used by medical directors and other health care professionals in making medical necessity and other coverage determinations. Please note the terms of a customer’s particular benefit plan document may differ significantly from the standard benefit plans upon which these coverage policies are based. For example, a customer’s benefit plan document may contain a specific exclusion related to a topic addressed in a coverage policy.

In the event of a conflict, a customer’s benefit plan document always supersedes the information in the coverage policy. In the absence of federal or state coverage mandates, benefits are ultimately determined by the terms of the applicable benefit plan document. Coverage determinations in each specific instance require consideration of:

1. The terms of the applicable benefit plan document in effect on the date of service
2. Any applicable laws and regulations
3. Any relevant collateral source materials including coverage policies
4. The specific facts of the particular situation

Coverage policies relate exclusively to the administration of health benefit plans. Coverage policies are not recommendations for treatment and should never be used as treatment guidelines.

This evidence-based medical coverage policy has been developed by eviCore, Inc. Some information in this coverage policy may not apply to all benefit plans administered by Cigna.

These guidelines include procedures eviCore does not review for Cigna. Please refer to the Cigna CPT code list for the current list of high-tech imaging procedures that eviCore reviews for Cigna.

CPT® (Current Procedural Terminology) is a registered trademark of the American Medical Association (AMA). CPT® five digit codes, nomenclature and other data are copyright 2017 American Medical Association. All Rights Reserved. No fee schedules, basic units, relative values or related listings are included in the CPT® book. AMA does not directly or indirectly practice medicine or dispense medical services. SP-1.1: General Considerations

- Before advanced diagnostic imaging can be considered, there must be an initial face-to-face clinical evaluation as well as a clinical re-evaluation after a trial of failed conservative therapy; the clinical re-evaluation may consist of a face-to-face evaluation or other meaningful contact with the provider’s office such as email, web or telephone communications.

- A face-to-face clinical evaluation is required to have been performed within the last 60 days before advanced imaging is considered. This may have been either the initial clinical evaluation or a clinical re-evaluation.

- The initial clinical evaluation should include a relevant history and physical examination (including a detailed neurological examination), appropriate laboratory studies, non-advanced imaging modalities, results of manual motor testing, the specific dermatomal distribution of altered sensation, reflex examination, and nerve root tension signs (e.g., straight leg raise test, slump test, femoral nerve tension test). The initial clinical evaluation must be face-to-face; other forms of meaningful contact (telephone call, electronic mail or messaging) are not acceptable as an initial evaluation.

- For those spinal conditions/disorders for which the Spine Imaging Guidelines require a plain x-ray of the spine prior to consideration of an advanced imaging study, the plain x-ray must be performed after the current episode of symptoms started or changed (See **SP-2.1: Anatomic Guidelines**).

- Clinical re-evaluation is required prior to consideration of advanced diagnostic imaging to document failure of significant clinical improvement following a recent (within 3 months) six week trial of provider-directed treatment. Clinical re-evaluation can include documentation of a face-to-face encounter or documentation of other meaningful contact with the requesting provider’s office by the individual (e.g., telephone call, electronic mail or messaging).

- Provider-directed treatment may include education, activity modification, NSAIDs (non-steroidal anti-inflammatory drugs), narcotic and non-narcotic analgesic medications, oral or injectable corticosteroids, a provider-directed home exercise/stretching program, cross-training, avoidance of aggravating activities, physical/occupational therapy, spinal manipulation, interventional pain procedures and other pain management techniques.

- Any bowel/bladder abnormalities or emergent or urgent indications should be documented at the time of the initial clinical evaluation and clinical re-evaluation.

- Altered sensation to pressure, pain, and temperature should be documented by the specific anatomic distribution (e.g., dermatomal, stocking/glove or mixed distribution).
Motor deficits (weakness) should be defined by the specific myotomal distribution (e.g., weakness of toe flexion/extension, knee flexion/extension, ankle dorsi/plantar flexion, wrist dorsi/palmar flexion) and gradation of muscle testing should be documented as follows:

**Grading of Manual Muscle Testing**

<table>
<thead>
<tr>
<th>Grade</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No evidence of muscle function</td>
</tr>
<tr>
<td>1</td>
<td>Muscle contraction but no or very limited joint motion</td>
</tr>
<tr>
<td>2</td>
<td>Movement possible with gravity eliminated</td>
</tr>
<tr>
<td>3</td>
<td>Movement possible against gravity</td>
</tr>
<tr>
<td>4</td>
<td>Movement possible against gravity with some resistance</td>
</tr>
<tr>
<td>5</td>
<td>Movement possible against gravity with full or normal resistance</td>
</tr>
</tbody>
</table>

Pathological reflexes (e.g. Hoffmann’s, Babinski, and Chaddock sign) should be reported as positive or negative.

Asymmetric reflexes and reflex examination should be documented as follows:

**Grading of Reflex Testing**

<table>
<thead>
<tr>
<th>Grade</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>A brisk response</td>
</tr>
<tr>
<td>3+</td>
<td>A very brisk response without clonus</td>
</tr>
<tr>
<td>4+</td>
<td>A tap elicits a repeating reflex (clonus)</td>
</tr>
</tbody>
</table>

Advanced diagnostic imaging is often urgently indicated and may be necessary if serious underlying spinal and/or non-spinal disease is suggested by the presence of certain individual factors referred to as “red flags.” See **SP-1.2: Red Flag Indications**.

Spinal specialist evaluation can be helpful in determining the need for advanced diagnostic imaging, especially for individuals following spinal surgery.

The need for repeat advanced diagnostic imaging should be carefully considered and may not be indicated if prior advanced diagnostic imaging has been performed. Requests for simultaneous, similar studies such as spinal MRI and CT need to be documented as required for preoperative surgical planning. These studies may be helpful in the evaluation of complex failed spinal fusion cases or needed for preoperative surgical planning when the determination of both soft tissue and bony anatomy is required.

Serial advanced imaging, whether CT or MRI, for surveillance of healing or recovery from spinal disease is not supported by the currently available scientific evidence-based medicine for the majority of spinal disorders.

Advanced imaging is generally unnecessary for resolved or improving spinal pain and/or radiculopathy.
For individuals experiencing chronic spine pain, advanced diagnostic imaging has not been shown to be of value in individuals with stable, longstanding spinal pain without neurological features or without clinically significant or relevant changes in symptoms or physical examination findings.

**Background and Supporting Information**

**Straight leg raise test** (also known as the Lasegue’s test) – With the individual in the supine position, the hip medially rotated and adducted, and the knee extended, the examiner flexes the hip until the individual complains of pain or tightness in the back or back of the leg. If the pain is primarily back pain, it is more likely a disc herniation or the pathology causing the pain is more central. If pain is primarily in the leg, it is more likely that the pathology causing the pressure on neurological tissues is more lateral. Disc herniation or pathology causing pressure between the two extremes are more likely to cause pain in both areas. The examiner then slowly and carefully drops the leg back (extends it) slightly until the individual feels no pain or tightness. The individual is then asked to flex the neck so the chin is on the chest, or the examiner may dorsiflex the individual’s foot, or both actions may be done simultaneously. Both of these maneuvers are considered to be provocative tests for neurological tissue.

**Slump test** – The individual is seated on the edge of the examination table with the legs supported, the hips in neutral position, and the hands behind the back. The examination is performed in sequential steps. First, the individual is asked to “slump” the back into thoracic and lumbar flexion. The examiner maintains the individual’s chin in neutral position to prevent neck and head flexion. The examiner then uses one arm to apply overpressure across the shoulders to maintain flexion of the thoracic and lumbar spines. While this position is held, the individual is asked to actively flex the cervical spine and head as far as possible (i.e., chin to chest). The examiner then applies overpressure to maintain flexion of all three parts of the spine (cervical, thoracic, and lumbar) using the hand of the same arm to maintain overpressure in the cervical spine. With the other hand, the examiner then holds the individual’s foot in maximum dorsiflexion. While the examiner holds these positions, the individual is asked to actively straighten the knee as much as possible. The test is repeated with the other leg and then with both legs at the same time. If the individual is unable to fully extend the knee because of pain, the examiner releases the overpressure to the cervical spine and the individual actively extends the neck. If the knee extends further, the symptoms decrease with neck extension, or the positioning of the individual increases the individual’s symptoms, then the test is considered positive.

**Femoral nerve tension test** (also known as the prone knee bending test) – The individual lies prone while the examiner passively flexes the knee as far as possible so that the individual’s heel rests against the buttock. At the same time, the examiner should ensure that the individual’s hip is not rotated. If the examiner is unable to flex the individual’s knee past 90 degrees because of a pathological condition in the hip, the test may be performed by passive extension of the hip while the knee is flexed as much as possible. The flexed knee position should be maintained for 45 to 60 seconds. Unilateral neurological pain in the lumbar area, buttock, and/or posterior thigh may indicate an L2
or L3 nerve root lesion. Pain in the anterior thigh indicates tight quadriceps muscles or stretching of the femoral nerve.

**Hoffmann’s sign** – The examiner holds the individual's middle finger and briskly flicks the distal phalanx. A positive test is noted if the interphalangeal joint of the thumb of the same hand flexes.

**Babinski’s sign** – The examiner runs a sharp instrument along the plantar surface of the foot from the calcaneus along the lateral border to the forefoot. A positive test occurs with extension of the great toe with flexion and splaying of the other toes. A negative test occurs with no movement of the toes at all or uniform bunching up of the toes.

**Chaddock sign** – The examiner strokes the lateral malleolus. A positive test occurs with extension of the great toe.

### SP-1.2: Red Flag Indications

*Red Flag Indications are intended to represent the potential for life or limb threatening conditions.* Red Flag Indications are clinical situations in which localized spine pain and associated neurological features are likely to reflect serious underlying spinal and/or non-spinal disease and warrant exception to the requirement for documented failure of six weeks of provider-directed treatment. Advanced diagnostic imaging of the symptomatic level is appropriate and/or work-up for a non-spinal source of spine pain for Red Flag Indications.

- Red Flag Indications include:
  - Motor Weakness
  - Aortic Aneurysm or Dissection
  - Cancer
  - Cauda Equina Syndrome
  - Fracture
  - Infection
  - Severe Radicular Pain

### Motor Weakness

(See **Grading of Manual Muscle Testing and Reflex Testing** in **SP-1.1: General Considerations**)

<td></td>
</tr>
<tr>
<td>□ A plan for urgent/emergent spinal surgery.</td>
<td></td>
</tr>
</tbody>
</table>

SP-1.3: Definitions

- **Radiculopathy**, for the purpose of this policy, is defined as the presence of pain resulting in significant functional limitations (i.e., diminished quality of life and impaired, age-appropriate activities of daily living), dysaesthesia(s) or paraesthesia(s) reported by the individual in a specified dermatomal distribution of an involved named spinal root(s) and **ONE or MORE** of the following:
  - Loss of strength of specific named muscle(s) or myotomal distribution(s) or demonstrated on detailed neurologic examination (within the prior 3 months), concordant with nerve root compression of the involved named spinal nerve root(s).
  - Altered sensation to light touch, pressure, pin prick or temperature demonstrated on a detailed neurologic examination (within the prior 3 months) in the sensory distribution concordant with nerve root compression of the involved named spinal nerve root(s).
  - Diminished, absent or asymmetric reflex(es) within the prior 3 months concordant with nerve root compression of the involved named spinal nerve root(s).
  - Either of the following:
    - A concordant radiologist’s interpretation of an advanced diagnostic imaging study (MRI or CT) of the spine demonstrating compression of the involved named spinal nerve root(s) or foraminal stenosis at the concordant level(s) (Performed within the prior 12 months).
    - Electrodiagnostic studies (EMG/NCV’s) diagnostic of nerve root compression of the involved named spinal nerve root(s). (Performed within the prior 12 months).
Radicular pain is pain which radiates to the upper or lower extremity along the course of a spinal nerve root, typically resulting from compression, inflammation and/or injury to the nerve root.

Radiculitis is defined, for the purpose of this policy, as radicular pain without objective neurological findings.

SP-2.1: Anatomic Guidelines

Anatomic regions of the spine/pelvis that are included in the following MRI and CT advanced diagnostic imaging studies:

- **Cervical spine:** from the skull base/foramen magnum through T1
- **Thoracic spine:** from C7 through L1
- **Lumbar spine:** from T12 through mid-sacrum
- **Pelvis:** includes hips, sacroiliac joints, sacrum, coccyx

CT or MRI Cervical and Thoracic Spine will image the entire spinal cord since the end of the spinal cord or conus medullaris usually ends at L1 in adults. Therefore, lumbar spine imaging is not needed when the goal is to image only the spinal cord unless there is known or suspected low lying conus medullaris (e.g. tethered cord).

Plain x-ray should be the initial evaluation for certain suspected spine conditions, including:

- See **SP-11: Pathological Spinal Compression Fractures**
- See **SP-8: Lumbar Spine Spondylolysis/Spondylolisthesis**
- See **SP-10.2: Inflammatory Spondylitis**
- See **SP-3.2: Neck (Cervical Spine) Trauma, SP-4.2: Upper Back (Thoracic Spine) Trauma, and SP-6.2: Low Back (Lumbar Spine) Trauma**
- See **SP-5.2: Coccydynia without Neurological Features**
- See **SP-14: Spinal Deformities (e.g. Scoliosis/Kyphosis) and PEDSP-4: Spinal Dysraphism**
- See **SP-10: Sacro-Iliac (SI) Joint Pain, Inflammatory Spondylitis/Sacroilitis and Fibromyalgia**
- See **SP-15: Post-Operative Spinal Disorders**

SP-2.2: MRI of the Spine

- See **Procedure Codes Associated with Spine Imaging**

MRI Spine is performed either without contrast, with contrast or without and with contrast. A “with contrast” study alone is appropriate only to complete a study begun without contrast. Contrast is generally not indicated for most disc and nerve root disorders, fractures and degenerative disease.

MRI Spine indications include:

- Evaluation of disc disease, spinal cord and nerve root disorders and most other spinal conditions including evaluation of congenital anomalies of the spine and spinal cord
- Suspicion for or surveillance of known spine/spinal canal/spinal cord neoplastic disease.
- Suspicion, diagnosis of or surveillance of spinal infections, multiple sclerosis or other causes of myelitis, syringomyelia, cauda equina syndrome or other “red flag” indications. See **SP-1.2: Red Flag Indications**.
Preoperative evaluation to define abnormal or variant spinal anatomy that could influence the outcome of a potential surgical procedure. See SP-16.1: Prior to Spine Surgery.

Spinal imaging for individuals having undergone recent spinal surgery e.g., laminectomy, discectomy, spinal decompression, when history and physical examination is suspicious for hematoma, post-surgical infection, or cerebrospinal fluid (CSF) leak.

Positional MRI:
- Positional MRI is also referred to as dynamic, weight-bearing or kinetic MRI. Currently, there is inadequate scientific evidence to support the medical necessity of this study. As such, it should be considered experimental or investigational.

SP-2.3: CT of the Spine
- See Procedure Codes Associated with Spine Imaging
- CT Spine indications include:
  - Individuals who cannot have MRI (with implanted ferromagnetic materials or electronically, magnetically or mechanically activated implanted devices that are not determined by the manufacturer as MRI compatible).
  - Any spinal trauma/fractures, especially spinal trauma/fractures that could result in spinal instability and spinal cord/spinal nerve compression.
  - Spinal neoplastic disease – primary or metastatic.
  - In conjunction with myelography or discography (See SP-2.4: CT/Myelography and SP-2.5: Lumbar Provocative Discography CT).
  - Preoperative evaluation to define abnormal or variant bony spinal anatomy that could influence the outcome of a potential surgical procedure (See SP-16.1: Prior to Spine Surgery).
  - To assess spinal fusions when pseudoarthrosis is suspected (not to be used for routine post-operative assessment where x-rays are sufficient and/or there are no concordant clinical signs or symptoms).
  - Congenital, developmental or acquired spinal deformity (See SP-14: Spinal Deformities (e.g. Scoliosis/Kyphosis)).
  - Spondylolysis when routine x-rays are negative and/or MRI is equivocal, indeterminate or non-diagnostic (See SP-8: Lumbar Spine Spondylolysis/Spondylolisthesis).
  - To evaluate calcified lesions, (e.g., osteophytes, ossification of the posterior longitudinal ligament [OPLL]).
**SP-2.4: CT/Myelography**

- See [Procedure Codes Associated with Spine Imaging](#).
- CT/Myelography is generally unnecessary as an initial study when a diagnostic quality MRI has been obtained.
- CT/Myelography indications include:
  - To clarify equivocal, indeterminate or non-diagnostic MRI findings or to further evaluate the significance of multiple spinal abnormalities.
  - When an MRI is contraindicated (See [SP-2.2: MRI of the Spine](#)).
  - Preoperative planning for spine surgery, (e.g., multilevel spinal stenosis or when a previous MRI is insufficient, equivocal, indeterminate or non-diagnostic). See [SP-16.1: Prior to Spine Surgery](#).
  - Evaluation after previous spinal surgery when an MRI without and with contrast is contraindicated or MRI results are equivocal, indeterminate or non-diagnostic.

  eviCore authorizes only the post-myelogram CT (i.e., CPT® 72126, CPT® 72129, and CPT® 72132) and not any other myelogram-related procedure codes (i.e., CPT® 72265 or CPT® 62284).

**SP-2.5: Lumbar Provocative Discography CT**

- eviCore authorizes only the post-lumbar discography CT procedure codes and not any other discography-related procedure codes. A post-lumbar discography CT is considered medically necessary following an approved discography and ALL of the following apply:
  - A post-discography CT is coded as without contrast.
  - A CT Lumbar Spine without contrast (CPT® 72131) is appropriate if verified to be performed as a post-discography CT.
  - When a post-discography CT is requested and the discography has already been approved eviCore will issue authorization for the post-discography CT procedure codes.

**Background and Supporting Information**

- Provocative Discography/CT is a controversial procedure purported to diagnose (or rule-out) a discogenic “pain generator.” i.e., the source of non-specific axial spinal pain. This diagnostic study, when reported as positive, is often used as an indication for spinal fusion in individuals with non-specific axial back pain.

- The following uses of discography are considered controversial:
  - To identify a symptomatic pseudoarthrosis in a failed spinal fusion.
  - To identify which of two herniated discs seen on MRI is symptomatic when not determined clinically or otherwise.
  - To confirm the discogenic nature of pain in an individual with an abnormal disc seen on MRI and to rule out pain from an adjacent disc level.
  - To confirm the presumptive diagnosis of “internal disc disruption”.
  - Discography of the cervical and/or thoracic spine.
SP-2.6: Ultrasound of the Spinal Canal

- Spinal canal ultrasound (CPT® 76800) describes the evaluation of the spinal cord (canal and contents) most often performed in newborns, infants, young children and intraoperatively.
- CPT® 76800 describes evaluation of the entire spine and should not be reported multiple times for imaging of different areas of the spinal canal.
- CPT® 76998, rather than CPT® 76800, should be used to report intraoperative spinal canal ultrasound (ultrasonic guidance). Intraoperative use of spinal ultrasound (CPT® 76998) would not require prior authorization by eviCore.

Indications for spinal canal ultrasound (CPT® 76800):
- This study is generally limited to infants, newborns and young children because of incomplete ossification of the vertebral segments surrounding the spinal cord, including the assessment of CSF in the spinal canal and for image-guided lumbar puncture.
- When ossification of the vertebral segments is incomplete for evaluation of suspected or known tethered cord (See PEDSP-5: Tethered Cord).
- Evaluation of suspected occult and non-occult spinal dysraphism (See PEDSP-4: Spinal Dysraphism).
- Evaluation of spinal cord tumors, vascular malformations and cases of birth-related trauma.
- Contraindicated for use in the adult spine for the assessment of spinal pain, radiculopathy, facet inflammation, nerve root inflammation, disc herniation, and soft tissue conditions surrounding the adult spine other than for superficial masses.

SP-2.7: Limitations of Spinal Imaging in Degenerative Disorders

- Non-specific axial spinal pain is ubiquitous. Advanced diagnostic imaging infrequently identifies the source of the spinal pain (pain generator).
- Incidental findings on MRI and CT, including bulging, protruding, extruding or herniated discs, are often non-concordant, asymptomatic and increase in incidence as the spine ages.
- In individuals with poorly defined clinical presentations, “abnormal” spinal advanced diagnostic imaging results are infrequently clinically concordant, significant, material or substantive and may even lead to inappropriate treatment.
- Performing advanced spinal imaging based only on the presence of spinal degenerative findings identified on x-rays is not generally indicated in individuals who are either asymptomatic or present with non-specific axial spinal pain.
SP-2.8: Miscellaneous Spinal Lesions

**Vertebral body hemangiomas:**
- Vertebral body hemangiomas are common and are generally benign and incidental findings on plain x-rays and advanced diagnostic imaging studies.
- If the appearance of a vertebral body hemangioma is typical on plain x-ray, further spinal advanced diagnostic imaging is not usually required, unless there are associated neurologic symptoms or signs on physical examination.
- If the appearance of a vertebral body hemangioma is atypical on plain x-ray, (with or without neurological signs or symptoms on physical exam, MRI without contrast or MRI without and with contrast is indicated.
- Occasionally, MRI may be equivocal, indeterminate or non-diagnostic and CT without contrast of the spinal area is indicated to help clarify the diagnosis.
- No follow-up imaging is necessary once the diagnosis of a vertebral body hemangioma is established without neurological features.

**Tarlov cysts:**
- Tarlov cysts are most often cystic dilatations of nerve root sleeves in the lumbar spine and sacrum.
- Controversy exists as to whether Tarlov cysts can result in neurologic signs and symptoms but they can result in erosion of the adjacent bone.
- Usually Tarlov cysts are benign, incidental findings on advanced diagnostic imaging studies. Further evaluation of a known or suspected Tarlov cyst can be performed with a MRI without and with contrast study (CPT® 72158) or with Lumbar CT/Myelography (CPT® 72132).

**Other spinal lesions:**
- MRI without and with contrast or a CT without contrast is appropriate if:
  - Other spinal lesions are seen on routine x-rays or a non-contrast MRI; and
  - These additional advanced imaging studies are recommended by a spine specialist or radiologist to further characterize or diagnose the lesion; or
  - Required for surgical planning.
**SP-2.9: MRA Spinal Canal**

- All requests for spinal MRA will be forwarded for Medical Director Review.
- MRA Spine imaging is utilized infrequently.
- Cerebrospinal Fluid (CSF) flow studies using MRI are included in CPT® codes 70551, 70552, and 70553 and should not be coded or reported separately.

**Indications may include:**

- Suspected spinal cord arteriovenous malformation (AVM) or arteriovenous fistula (AVF):
  - MRI Spine of the relevant spine region without and with contrast should be the initial imaging study.
  - If suspicion for a spinal AVM or AVF is high based upon the results of the spine MRI, catheter angiography is recommended (CPT® 72159 or CPT® 70496).
- Subarachnoid hemorrhage where no brain aneurysm has been previously identified
  - Catheter angiography (CPT® 70496) should be performed and is the most definitive study to define possible spinal pathology resulting in a spinal canal subarachnoid hemorrhage.
  - See HD-1.5: General Guidelines - CT and MR Angiography: (CTA and MRA)
  - See HD 12.1: Intracranial Aneurysms
- Preoperative planning
  - MRA Spinal canal may be useful in identifying major intercostal feeder vessels to the spinal cord prior to surgical procedures that might interfere with this blood supply to the spinal cord. However, catheter angiography (CPT® 72159) is generally a more definitive study for this purpose.

**SP-2.10: Spine PET**

- At the present time there is controversy regarding spine PET due to inadequate scientific evidence to support the medical necessity of PET for the routine assessment of spinal disorders, other than for neoplastic disease.
- See ONC-31.5: Bone (including Vertebral) Metastases
- Spine PET should be considered experimental or investigational and will be forwarded to Medical Director Review.

**SP-2.11: Cone-beam CT**

- Cone-beam CT for imaging of the cervical spine should be considered experimental or investigational and will be forwarded to Medical Director Review

**SP-3.1: Neck (Cervical Spine) Pain without and with Neurological Features (Including Stenosis)**

*All* of the following are required prior to advanced imaging:

- Initial clinical evaluation performed.
- A face-to-face evaluation within the last 60 days.
- The initial evaluation is not required within the last 60 days if another face-to-face evaluation was performed in that time frame. This may be satisfied by the initial evaluation, re-evaluation or another visit.

Failure of recent (within 3 months) 6-week trial of provider-directed treatment

Clinical re-evaluation after treatment period (may consist of a face-to-face evaluation or other meaningful contact, See **SP-1.1: General Considerations**)

**Advanced Diagnostic Imaging:**

<table>
<thead>
<tr>
<th>MRI Cervical Spine, without contrast (CPT®72141).</th>
</tr>
</thead>
</table>

**Comments:**

CT Cervical Spine without contrast (CPT®72125) or CT Myelography (CPT®72126) is appropriate when MRI is contraindicated.

For surgery criteria, See

- CMM-601: Anterior Cervical Discectomy and Fusion
- CMM-602: Cervical Total Disc Arthroplasty
- CMM-604: Initial Posterior Cervical Decompression with or without Fusion
- CMM-605: Cervical Microdiscectomy

**SP-3.2: Neck (Cervical Spine) Trauma**

*All* of the following are required prior to advanced imaging:

- Initial clinical evaluation performed.
- A face-to-face evaluation within the last 60 days.
- The initial evaluation is not required within the last 60 days if another face-to-face evaluation was performed in that time frame. This may be satisfied by the initial evaluation, re-evaluation or another visit.

Failure of recent (within 3 months) 6-week trial of provider-directed treatment

Clinical re-evaluation after treatment period (may consist of a face-to-face evaluation or other meaningful contact, See **SP-1.1: General Considerations**)

Plain x-rays of cervical spine negative for fracture

</thead>
<tbody>
<tr>
<td>MRI Cervical Spine without contrast (CPT®72141) and CT Cervical Spine without contrast (CPT®72125) for individuals with ankylosing spondylitis.</td>
</tr>
</tbody>
</table>

**Comments:**

Plain x-rays and a 6 week trial of provider-directed treatment and clinical re-evaluation are *not* required for individuals with a high risk mechanism of cervical spine injury within the last 3 months (See below**). **High risk mechanisms of cervical spine injury may include:**

- Head trauma and/or maxillofacial trauma
- Pedestrian in a motor vehicle accident
- Fall from elevation ≥3 feet/5 stairs
- Diving accident
Head-on motor vehicle collision without/with airbag deployment
- Rollover motor vehicle collision
- Ejection from the vehicle in a motor vehicle collision
- High speed of the vehicle at the time of collision
- Not wearing a seatbelt/shoulder harness in a motor vehicle collision
- Individuals with ankylosing spondylitis are at high risk of cervical spine fractures even with minor direct/indirect trauma to the cervical spine which can result in quadriplegia

Red Flag Indications: See SP-1.2: Red Flag Indications

Background and Supporting Information

- Pain radiation patterns from the cervical spine area into the thoracic spine area do not necessarily justify the addition of thoracic spine advanced diagnostic imaging.
- Cervical radiculopathy is often confused with shoulder disorders, brachial plexopathy, peripheral nerve entrapment and/or motor/sensory neuropathies. Electrodiagnostic testing (EMGs/NCVs) is generally used to confirm, not establish, a diagnosis of peripheral nerve entrapment and/or a motor/sensory neuropathy based upon history and physical examination findings. Electrodiagnostic testing is often considered when advanced imaging of the spine does not reveal neurocompressive pathology and/or after 6 weeks of unimproved symptoms of extremity pain, weakness, numbness and/or tingling.

</tbody>
</table>

**Advanced Diagnostic Imaging:** MRI Thoracic Spine without contrast (CPT® 72146) or CT Thoracic Spine without contrast (CPT® 72128).

**Red Flag Indications:** See **SP-1.2: Red Flag Indications**

**Background and Supporting Information**
- Thoracic radiculopathy presents with pain radiation from the thoracic spine around the trunk. At upper thoracic spine levels, the pain radiation is from the thoracic spine around the rib cage following the sensory distribution of an intercostal nerve.
- Advanced diagnostic imaging is generally not appropriate in evaluation of axial low back pain with radiation toward the thoracic region unless there are documented clinical features indicating a thoracic spine disorder.

Clinical re-evaluation after treatment period (may consist of a face-to-face evaluation or other meaningful contact, See SP-1.1: General Considerations).

Plain x-rays of lumbar spine negative for fracture.

Advanced Diagnostic Imaging: MRI Lumbar Spine without contrast (CPT® 72148) or CT Lumbar Spine without contrast (CPT® 72131).

Red Flag Indications: See SP-1.2: Red Flag Indications

Definitions of radiculopathy, radiculitis and radicular pain: See SP-1.3: Definitions

Sciatic Neuropathy, Femoral Neuropathy, Peroneal Neuropathy and Meralgia Paresthetica: See PN-2: Focal Neuropathy

Lumbar and/or Lumbosacral Plexopathy: See PN-5: Lumbar and Lumbosacral Plexus

Advanced imaging of the hip or pelvis is not generally required in the evaluation of apparent lumbar radiculopathy unless a separate recognized indication for such studies is documented. See MS-24: Hip in the Musculoskeletal Imaging Guidelines.
References

**SP-7.1: Myelopathy**

- Myelopathy is the development of abnormal spinal cord function with long tract signs usually secondary to spinal cord compression, but also inflammation (transverse myelitis, MS, etc.), neoplastic disease or spinal cord infarction.

- Examination findings may include loss of manual dexterity, spastic legs and ataxia with hyperreflexia and upgoing toes (positive Babinski), Hoffmann’s sign, sustained clonus, Lhermitte’s sign, crossed radial reflex, inverted radial reflex and finger escape sign. Sensory level and urinary incontinence/retention may be seen. Advanced imaging is generally appropriate in the initial evaluation of documented or reasonably suspected myelopathy.

- MRI Cervical, Thoracic, and Lumbar Spine without contrast, or without and with contrast, are appropriate for:
  - Initial evaluation of reasonably suspected myelopathy.
  - Suspected tethered cord.
  - Post-traumatic syrinx with increased spinal pain or a worsening neurological symptoms.
  - Sustained, prominent, and unexplained Lhermitte’s sign.
  - Unexplained Babinski’s sign.
  - Hoffmann’s sign.

- Conservative treatment is not a requirement for advanced imaging in individuals with potential myelopathy.

- CT/Myelography scan can also be considered, especially for surgical planning.

For surgery criteria, See
- CMM-601: Anterior Cervical Discectomy and Fusion
- CMM-602: Cervical Total Disc Arthroplasty
- CMM-604: Posterior Cervical Decompression with or without Fusion
- CMM-605: Cervical Microdiscectomy

**Background and Supporting Information**

**Lhermitte’s sign** – With the individual in the long leg sitting position on the examination table, the examiner passively flexes the individual’s head and one hip simultaneously with the leg kept straight. A positive test occurs if there is sharp pain down the spine and into the upper or lower extremities.

**Babinski’s sign** – The examiner runs a sharp instrument along the plantar surface of the foot from the calcaneus along the lateral border to the forefoot. A positive test occurs with extension of the great toe with flexion and splaying of the other toes. A negative test occurs with no movement of the toes at all or uniform bunching up of the toes.

**Hoffman’s sign** – The examiner holds the individual’s middle finger and briskly flicks the distal phalanx. A positive test is noted if the interphalangeal joint of the thumb of the same hand flexes.

### SP-8: Lumbar Spine

**Spondylolysis/Spondylolisthesis**

<table>
<thead>
<tr>
<th>SP-8.1: Spondylolysis</th>
<th>39</th>
</tr>
</thead>
<tbody>
<tr>
<td>SP-8.2: Spondylolisthesis</td>
<td>40</td>
</tr>
</tbody>
</table>
SP-8.1: Spondylolysis

- Spondylolysis is most often an incidental finding on plain x-rays, and advanced imaging is generally not indicated.

- If plain x-rays are negative, equivocal or indeterminate and clinical suspicion is high:
  - 99mTc-MDP SPECT bone scan (CPT® 78320) is indicated to identify stress reaction in early spondylolysis cases which are radiographically occult.
  - MRI Lumbar Spine without contrast (CPT® 72148) is indicated for ANY of the following:
    - SPECT bone scan is negative
    - To evaluate for stress reaction in bone, to visualize nerve roots
    - There is a documented need for preoperative planning
    - There is treatment failure following 6 weeks immobilization with a spinal orthosis and provider-directed treatment with clinical re-evaluation
      - Note that MRI is not appropriate in the early diagnosis of spondylolysis due to the potential for false negative results.

- CT Lumbar Spine without contrast (CPT® 72131) for ANY of the following:
  - MRI is contraindicated
  - SPECT bone scan is negative
  - To evaluate a lesion seen on SPECT bone scan
  - To evaluate bony anatomy
  - There is a documented need for preoperative planning
  - There is treatment failure following 6 weeks immobilization with a spinal orthosis and provider-directed treatment with clinical re-evaluation. See SP-1.2: Red Flag Indications.

- For pediatric spondylolysis, See PEDSP-2.4: Spondylolysis

- Bony healing cannot be achieved non-surgically in an established well defined isthmic pars interarticularis defect whether it is developmental or the result of a pars interarticularis fracture non-union. Repeat advanced diagnostic imaging is not medically necessary in this setting.
  - Repeat CT Lumbar Spine without contrast (CPT® 72131) of the symptomatic spinal level is indicated to monitor healing of a pars interarticularis fracture that was determined to have healing potential on a prior CT (i.e., non-sclerotic lesion).

- For surgery criteria, See
  - CMM-603: Electrical and Low Frequency Ultrasound Bone Growth Stimulation (Spine)
  - CMM-609: Lumbar Fusion (Arthrodesis)
SP-8.2: Spondylolisthesis

CT Lumbar Spine without contrast (CPT® 72131) or MRI Lumbar Spine without contrast (CPT® 72148) can be considered after plain x-ray for the following:

- Failure of 6 week trial of provider-directed treatment and clinical re-evaluation (See SP-1.1: General Considerations); or
- Preoperative evaluation; or
- See SP-1.2: Red Flag Indications

For surgery criteria, See
- CMM-608: Lumbar Decompression
- CMM-609: Lumbar Fusion (Arthrodesis)

Background and Supporting Information

Stress reactions and stress fractures of the pars interarticularis are most common in athletes and others whose activities involve repetitive flexion/extension loading of the lumbar spine and may be acute or chronic and unilateral or bilateral. Pars interarticularis defects can be an incidental finding on plain x-rays and is frequently asymptomatic.

Spondylolisthesis is the forward (anterolisthesis) or backward (retrolisthesis, usually not clinically significant) displacement of one vertebra in relation to an adjacent vertebra, most commonly at L4-5 and L5-S1, although other levels of the spine may be involved. Spondylolisthesis is often an incidental finding on plain x-ray and is frequently asymptomatic.

References
**SP-9.1: Lumbar Spinal Stenosis**

- MRI Lumbar Spine without contrast (CPT® 72148) or CT Lumbar Spine without contrast (CPT® 72131) is appropriate for those individuals with clinical suspicion of lumbar spinal stenosis if:
  - Failure of 6 week trial of provider-directed treatment and clinical re-evaluation (See **SP-1.1: General Considerations**); or
  - Red Flag Indications (See **SP-1.2: Red Flag Indications**); or
  - Severe symptoms of neurogenic claudication restricting normal activity or requiring the frequent use of narcotic analgesics.

- A CT/Myelogram Lumbar Spine (CPT® 72132) may also be considered for individuals who have failed 6-weeks of provider-directed treatment if requested by the operating surgeon for surgical planning, especially for multi-level lumbar spinal stenosis.

- For surgery criteria, See:
  - **CMM-608: Lumbar Decompression**
  - **CMM-609: Lumbar Fusion (Arthrodesis)**

**Background and Supporting Information**

Lumbar spinal stenosis refers to a decrease in the space available for the neural elements within the spinal canal that include spinal nerve roots and the cauda equina. It is usually a degenerative condition of the aging spine which can be asymptomatic or a common cause of buttock/low back and/or leg pain (neurogenic claudication) in this population. Neurogenic claudication is a common symptom of lumbar spinal stenosis that is aggravated by walking, especially down hills or stairs, with prolonged standing and is often relieved by sitting and bending forward. Neurogenic claudication should be differentiated from vascular claudication (leg/calf pain) that is often aggravated by walking and relieved fairly rapidly by stopping and rest. The differential diagnosis for lumbar spinal stenosis should include peripheral vascular disease, hip disorders and peripheral neuropathy.

</tbody>
</table>
SP-10.1: Sacro-Iliac (SI) Joint Pain/Sacroiliitis

- CT Pelvis without contrast (CPT® 72192) or MRI Pelvis without contrast (CPT® 72195) is appropriate if:
  - Initial plain x-rays are equivocal or not diagnostic;
  - Failure of 6 weeks of provider-directed treatment and clinical re-evaluation (See SP-1.1: General Considerations); or
  - Any ONE of the following:
    - Fractures of the sacrum or sacroiliac joint(s); or
    - See SP-1.2: Red Flag Indications; or
    - Preoperative planning
  - MRI Pelvis without and with contrast as indicated for pediatric individuals with juvenile idiopathic arthritis.

- Suspicion of neoplastic, inflammatory, or infectious disease:
  - MRI Pelvis without and with contrast (CPT® 72197) or MRI Pelvis without contrast (CPT® 72195)
    - CT Pelvis without contrast (CPT® 72192) if MRI is contraindicated

See MS-15.1: Rheumatoid Arthritis (RA) and Inflammatory Arthritis

SP-10.2: Inflammatory Spondylitis

- Initial plain x-rays are equivocal or not diagnostic.
  - MRI without and with contrast or MRI without contrast of the affected spinal region.
  - CT without contrast of the affected spinal region if MRI is contraindicated
  - MRI Cervical Spine without contrast (CPT® 72141) and CT Cervical Spine without contrast (CPT® 72125) if an individual with documented ankylosing spondylitis reports neck pain following any head/maxillofacial/neck injury.

SP-10.3: Fibromyalgia

- Advanced diagnostic imaging is not supported by the scientific evidence for the evaluation and treatment of fibromyalgia.

Background and Supporting Information

- Sacroiliitis can present with pain localized to the SI joint or referred pain to the buttock and/or posterior thigh without neurologic signs or symptoms. Affected individuals can often point to the SI joint as the pain source. Provocative and/or therapeutic SI joint anesthetic/corticosteroid injections can have diagnostic value.

- There is no evidence demonstrating that advanced diagnostic imaging substantiates changes to individual management decisions in individuals with proven SI joint disorders when visible on routine plain x-rays.
MRI has shown inflammatory changes in the SI joints prior to visible x-ray changes in several studies. However, the ability of MRI to characterize inflammation in early ankylosing spondylitis, the ability of MRI to predict erosive changes, and the value of monitoring treatment effects using serial MRI studies remains controversial and investigational in adults.

References
SP-11: Pathological Spinal Compression Fractures

SP-11.1: Pathological Spinal Compression Fractures
SP-11.1: Pathological Spinal Compression Fractures

MRI without contrast or CT without contrast of the affected spinal region can be considered after plain x-ray evaluation and the location of the individual’s spinal pain is concordant with the spinal x-rays for any one of the following:

- X-rays reveal a new spinal compression fracture; or
- X-rays are non-diagnostic and severe spinal pain persists for more than one week in an individual already predisposed to low energy/insufficiency fractures; or
- The acuity of the spinal compression fracture deformity on plain x-ray is indeterminate, or
- Surgical planning following known insufficiency spinal compression fractures in individuals who are candidates for kyphoplasty, vertebroplasty or other spine surgical procedures; or
- See SP-1.2: Red Flag Indications

For surgery criteria, See CMM-607: Primary Vertebral Augmentation

Background and Supporting Information

Insufficiency/low energy spinal compression fractures of the spine occur due to the lack of structural integrity to withstand physiologic loads and minor spinal trauma. Low bone mineral density is the primary etiology for most of these fractures but could also occur in the setting of other bone disease and medical conditions, in addition to neoplastic disease and infection. Sudden localized back pain, with or without trauma, is a typical presentation of insufficiency/low energy spinal compression fractures and can often be an incidental finding on plain x-rays and can be asymptomatic.

- For guidelines regarding advanced diagnostic imaging in this clinical setting, See ONC-31.6: Spinal Cord Compression.

- For metastatic disease of the spine without neurological signs or symptoms:
  - See ONC-31.5: Bone (including Vertebral) Metastases for advanced diagnostic imaging guidelines in individuals with spinal pain with a history of primary or metastatic neoplastic disease, especially cancer of the breast, lung, thyroid, kidney and prostate.
### SP-13: Spinal Canal/Cord Disorders (e.g. Syringomyelia)

<table>
<thead>
<tr>
<th>Section</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>SP-13.1: Initial Imaging Pathway</td>
<td>50</td>
</tr>
<tr>
<td>SP-13.2: Follow-up imaging</td>
<td>50</td>
</tr>
</tbody>
</table>
SP-13.1: Initial Imaging Pathway

- MRI Cervical Spine without and with contrast (CPT® 72156) when syringomyelia is suspected.
- Once a syrinx is identified by the initial MRI Cervical Spine without and with contrast:
  - MRI Brain, usually without contrast (CPT® 70551) to evaluate for syringobulbia; and
  - MRI Thoracic Spine without and with contrast (CPT® 72157) to define the lower most extent of the syrinx or to identify a skip lesion.
  - Advanced diagnostic imaging of the lumbar spine is generally not indicated unless tethered cord is suspected.

SP-13.2: Follow-up imaging

- MRI Cervical Spine without contrast (CPT® 72141) and MRI Brain without contrast (CPT® 70551) and/or MRI Thoracic Spine without contrast (CPT® 72146) when involved.
  - If there is a concern for malignancy, imaging can be performed without and with contrast.
  - Annual imaging until non-progression of the syringomyelia is established.
  - Following surgical treatment (including posterior fossa decompression).
  - Advanced diagnostic imaging every three years for life can be performed once non-progression of the syringomyelia is established.
  - Repeat advanced diagnostic imaging is appropriate when there is evidence of neurologic deterioration.
  - Repeat advanced diagnostic imaging in spinal cord injury individuals with post-traumatic syrinx is not appropriate without evidence of neurological deterioration.

Background and Supporting Information
Syringomyelia may begin to form in childhood but rarely becomes symptomatic before the adult years.

SP-14: Spinal Deformities (e.g. Scoliosis/Kyphosis)

SP-14.1: Spinal Deformities (e.g., Scoliosis/Kyphosis)  52
SP-14.2: Revision Spinal Deformity Surgery  52
SP-14.1: Spinal Deformities (e.g., Scoliosis/Kyphosis)

- MRI without contrast or MRI without and with contrast of the affected spinal regions after plain x-rays (e.g., Cobb radiographs) of the affected spinal regions:
  - For preoperative evaluation; or
  - For cases of congenital scoliosis and other atypical curves that may be associated with spinal canal/cord pathology such as tethered cord, syringomyelia, diastematomyelia, or tumors; or
  - For cases of scoliosis when there are associated neurologic signs and symptoms on physical examination; or
  - Scoliosis with a convex left thoracic curve due to a high association of a convex left thoracic curve with underlying spinal canal/cord pathology.

- CT of the affected spinal regions (contrast as requested) is appropriate in cases with a complex osseous deformity for preoperative evaluation.

- CTA or MRA is not medically necessary for preoperative planning for initial anterior spinal surgery for surgical correction of spinal deformities.

SP-14.2: Revision Spinal Deformity Surgery

- If requested by the operating surgeon, the following studies for preoperative planning revision anterior spinal surgery:
  - CTA Pelvis (CPT® 72191) and/or CTA Abdomen (CPT® 74175); or
  - MRA Pelvis (CPT® 72198) and/or MRA Abdomen (CPT® 74185)

Background and Supporting Information

Scoliosis is defined as a curvature of the spine in the coronal plane. Scoliosis can involve any or all levels of the spine but generally involves the thoracic and/or lumbar spine. Scoliosis initially occurs in the pediatric and adolescent population and persists throughout life. If scoliosis begins in adulthood, it is usually secondary to neurologic disorders (e.g., posttraumatic paralysis) or degenerative spondylosis. Sagittal plane spinal deformity (e.g., kyphosis, hyperlordosis) may be associated with scoliosis.

| SP-15.4: Revision Fusion Surgery | 56 |
*Following plain x-rays of the affected spinal regions post-surgical, See SP-2.1 Anatomic Guidelines.

**SP-15.1: Greater than Six Months Post-Operative**

- MRI without and with contrast, MRI without contrast, or CT without contrast of the affected spinal region(s) when:
  - Individual is more than six months post-operative; and
  - No significant improvement after a recent (within 3 months) six week trial of provider-directed treatment with clinical re-evaluation; or
  - See SP-1.2: Red Flag Indications

**SP-15.2: Routine: Post-Fusion Imaging**

- Requests will be forwarded to Medical Director Review. Following a clinically successful spinal fusion, advanced diagnostic imaging is generally not indicated.

- PET is not currently indicated for the routine assessment of spinal fusions or unsuccessful spine surgery (See SP-1.2: Red Flag Indications). Requests for PET will be forwarded to Medical Director Review.

**SP-15.3: Prolonged Intractable Pain Following Spinal Surgery Within Six Months**

**Open discectomy and laminectomy:**

- MRI without and with contrast of the affected spinal region(s) if there are residual, new, recurrent, or worsening symptoms related to the surgical site.
  - CT/Myelography of the affected spinal region(s) if MRI is contraindicated.

**Spinal fusions with or without Open Discectomy and/or Laminectomy:**

- These can be challenging problems that may require more than one advanced imaging study. Requests will be forwarded to Medical Director Review.

- For surgery criteria, See
  - CMM-601: Anterior Cervical Discectomy and Fusion
  - CMM-604: Posterior Cervical Decompression with or without Fusion
  - CMM-605: Cervical Microdiscectomy
  - CMM-606: Lumbar Microdiscectomy
  - CMM-608: Lumbar Decompression
  - CMM-609: Lumbar Fusion (Arthrodesis)
SP-15.4: Revision Fusion Surgery

If requested by the operating surgeon, the following studies for preoperative planning prior to surgical revision of a lumbar anterior spinal arthrodesis.

- CTA Pelvis (CPT® 72191) and/or CTA Abdomen (CPT® 74175); or
- MRA Pelvis (CPT® 72198) and/or MRA Abdomen (CPT® 74185)

For surgery criteria, See
- CMM-601: Anterior Cervical Discectomy and Fusion
- CMM-604: Posterior Cervical Decompression with or without Fusion
- CMM-609: Lumbar Fusion (Arthrodesis)

SP-16.1: Prior to Spine Surgery

- MRI/CT should be performed within the past six (6) months for preoperative planning prior to spine surgery when the criteria for advanced imaging studies of the spine are met as otherwise stated in the Spine Imaging Guidelines. (See SP-2.2: MRI of the Spine, SP-2.3: CT of the Spine, SP-2.4: CT/Myelography)

- MRA and CTA are generally not indicated for preoperative planning of initial anterior spinal surgery unless abnormal vasculature is known or reasonably anticipated. Requests will be forwarded to Medical Director Review.

- For surgery criteria, See
  - CMM-601: Anterior Cervical Discectomy and Fusion
  - CMM-604: Posterior Cervical Decompression with or without Fusion
  - CMM-605: Cervical Microdiscectomy
  - CMM-606: Lumbar Microdiscectomy
  - CMM-608: Lumbar Decompression
   - CMM-609: Lumbar Fusion (Arthrodesis)

SP-16.2: Prior to Interventional Spinal Injections

- Advanced diagnostic imaging studies of the spine are not required prior to facet joint injections, medial branch blocks or radiofrequency ablations unless the criteria for advanced imaging studies of the spine are met as otherwise stated in the Spine Imaging Guidelines.

- Advanced diagnostic imaging studies of the cervical spine and/or thoracic spine are indicated within 12 months prior to interlaminar or transforaminal epidural steroid injections of the cervical and/or thoracic spine when the criteria for advanced imaging studies of the spine are met as otherwise stated in the Spine Imaging Guidelines.

- Advanced diagnostic imaging studies of the lumbar spine are indicated prior to transforaminal epidural steroid injections of the lumbar spine when the criteria for advanced imaging studies of the spine are met as otherwise stated in the Spine Imaging Guidelines.

- Advanced diagnostic imaging studies of the lumbar spine are not required prior to lumbar spine interlaminar or caudal epidural steroid injections unless the criteria for advanced imaging studies of the spine are met as otherwise stated in the Spine Imaging Guidelines.

- For an individual with evidence of symptomatic spinal stenosis, MRI or CT with or without myelography demonstrating severe spinal stenosis at the level to be treated within the past twelve (12) months is required for an initial trial of a transforaminal, interlaminar or caudal epidural steroid injection when ALL of the following criteria are met:
  - Diagnostic evaluation has ruled out other potential causes of pain
- Significant functional limitations resulting in diminished quality of life and impaired age-appropriate activities of daily living (ADLs)
- Failure of at least four (4) weeks of conservative treatment (e.g., exercise, physical methods including physical therapy and/or chiropractic care, NSAIDS and/or muscle relaxants).

See SP-1.2: Red Flag Indications for severe radicular pain

- For interventional pain criteria, See
  - CMM-200: Epidural Steroid Injection
  - CMM-201: Facet Joint Injections
  - CMM-208: Radiofrequency Joint Ablation/Denervation

**SP-16.3: Prior to Spinal Cord Stimulator (SCS) Placement/Removal**

- MRI Thoracic Spine without contrast (CPT® 72146) is generally the study of choice prior to SCS placement. CT Thoracic Spine without contrast (CPT® 72128) or CT/Myelography Thoracic Spine (CPT® 72129) are alternatives.
- Imaging of the lumbar spine is not indicated for placement or removal of spinal cord stimulators.
- Requests for advanced diagnostic imaging of the cervical spine prior to SCS placement will be forwarded to Medical Director Review.
- For interventional pain criteria, See CMM-211: Spinal Cord Stimulators

**SP-16.4: Following Vertebral Augmentation Procedures**

- CT without contrast of the affected spinal region(s) within 24 hours post-procedure to evaluate neurologic sequelae resulting from cement extravasation.
- For surgery criteria, See CMM-607: Primary Vertebral Augmentation

**Background and Supporting Information**

MRI has not been shown to change the outcome of interventional pain procedures in recent scientific evidence-based studies and without substantial change in the clinical picture or intervening surgery. Repeat advanced diagnostic imaging studies are not necessary with each spinal injection or series of spinal injections.
