Cigna Medical Coverage Policies – Radiology Pediatric and Special Populations Oncology Imaging Guidelines

Effective April 1, 2023

Instructions for use

The following coverage policy applies to health benefit plans administered by Cigna. Coverage policies are intended to provide guidance in interpreting certain standard Cigna benefit plans and are used by medical directors and other health care professionals in making medical necessity and other coverage determinations. Please note the terms of a customer's particular benefit plan document may differ significantly from the standard benefit plans upon which these coverage policies are based. For example, a customer's benefit plan document may contain a specific exclusion related to a topic addressed in a coverage policy.

In the event of a conflict, a customer's benefit plan document always supersedes the information in the coverage policy. In the absence of federal or state coverage mandates, benefits are ultimately determined by the terms of the applicable benefit plan document. Coverage determinations in each specific instance require consideration of:

- 1. The terms of the applicable benefit plan document in effect on the date of service
- 2. Any applicable laws and regulations
- 3. Any relevant collateral source materials including coverage policies
- 4. The specific facts of the particular situation

Coverage policies relate exclusively to the administration of health benefit plans. Coverage policies are not recommendations for treatment and should never be used as treatment guidelines.

This evidence-based medical coverage policy has been developed by eviCore, Inc. Some information in this coverage policy may not apply to all benefit plans administered by Cigna.

These guidelines include procedures eviCore does not review for Cigna. Please refer to the <u>Cigna CPT</u> <u>code list</u> for the current list of high-tech imaging procedures that eviCore reviews for Cigna.

Abbreviations for Pediatric and Special Populations Oncology Imaging Guidelines			
AFP	Alpha-fetoprotein (tumor marker)		
ALCL	Anaplastic Large Cell Lymphoma		
ALL	Acute Lymphoblastic Leukemia		
AML	Acute Myelogenous Leukemia		
β-hCG	human chorionic gonadotropin beta-subunit (tumor marker)		
BKL	Burkitt's lymphoma		
BWT	bilateral Wilms tumor		
CCSK	Clear Cell Sarcoma of the Kidney		
CNS	central nervous system		
COG	Children's Oncology Group		
CPT®	Current Procedural Terminology; trademark of the American Medical Association		
CSF	cerebrospinal fluid		
СТ	computed tomography		
CXR	chest x-ray		
DAWT	diffuse anaplasia Wilms tumor		
ESFT	Ewing Sarcoma Family of Tumors		
FAWT	focal anaplasia Wilms tumor		
FHWT	favorable histology Wilms tumor		
HL	Hodgkin lymphoma		
HSCT	hematopoietic stem cell transplant (bone marrow or peripheral blood)		
HVA	homovanillic acid		
LL	lymphoblastic lymphoma		
MIBG	metaiodobenzylguanidine (nuclear scan using ¹²³ I or ¹³¹ I)		
MPNST	malignant peripheral nerve sheath tumor		
MRI	magnetic resonance imaging		
NBL	neuroblastoma		
NED	no evidence of disease		
NHL	non-Hodgkin lymphoma		
NPC	nasopharyngeal carcinoma		
NRSTS	nonrhabdomyosarcomatous soft tissue sarcomas		
OS	osteosarcoma		
PET	positron emission tomography		
PMBCL	primary mediastinal B-cell lymphoma		
PNET	primitive neuroectodermal tumor		
RCC	renal cell carcinoma		
RMS	rhabdomyosarcoma		
US	ultrasound		
VMA	vannilylmandelic acid		
WBC	white blood cell count		
XRT	radiation therapy

PEDONC-1.5: Diagnostic Radiation Exposure in Pediatric	
Oncology	19

PEDONC-1.0: General Guidelines

- A recent clinical evaluation (within 60 days) or meaningful contact (telephone call, electronic mail or messaging) should be performed prior to considering advanced imaging, unless the individual is undergoing guideline-supported scheduled off therapy surveillance evaluation or cancer screening. The clinical evaluation may include a relevant history and physical examination, including biopsy, appropriate laboratory studies, and results of non-advanced or advanced imaging modalities.
 - Because of the relatively small number of childhood cancer treatment centers, it is common to combine off-therapy visits with imaging and other subspecialist visits to accommodate families traveling long distances for their child's care.
- Unless otherwise stated in the disease-specific guideline, a histological confirmation of malignancy (or recurrence) and the stage of disease is required to perform a medical necessity review of the requested imaging.
- Unless otherwise stated in the disease-specific guideline, advanced imaging of asymptomatic individuals is not routinely supported without signs or symptoms of systemic involvement of cancer.
- Conventional imaging performed prior to diagnosis should not be repeated unless there is a delay of at least 6 weeks since previous imaging and treatment initiation or there are new or significantly worsening clinical signs or symptoms
- ➤ Unless otherwise stated in the diagnosis-specific guidelines, imaging for treatment response can be approved after every 2 cycles, which is usually ~6 weeks of therapy for solid tumors and usually ~8 to 12 weeks for CNS tumors
- Unless otherwise specified for a specific cancer type, once PET has been documented to be negative for a given patient's cancer or all PET-avid disease has been surgically resected, PET should not be used for continued disease monitoring or surveillance unless one of the following applies:
 - Conventional imaging (CT, MRI, US, plain film) reveals findings that are inconclusive or suspicious for recurrence
 - Residual mass that has not changed in size since the last conventional imaging does not justify PET imaging
 - PET avidity in a residual mass at the end of planned therapy is not an indication for PET imaging during surveillance.

Clarification of phases of therapy

Phases of Oncology Imaging	Definition
Screening	 Imaging requested for individuals at increased risk for a particular cancer in the absence of known clinical signs or symptoms Screening using advancing imaging is only supported for conditions listed in PEDONC-2: Screening Imaging in Cancer Predisposition Syndromes
Suspected/Initial Staging	 All imaging studies requested from the time cancer is first clinically suspected until the initiation of specific treatment CT Chest prior to anesthesia for biopsy or resection of solid tumors and CTs of other involved body areas are generally indicated and should be performed concurrently Metastatic CNS imaging and nuclear medicine imaging are generally deferred until after a histologic diagnosis is made, unless otherwise indicated by diagnosis-specific guideline
Treatment Response	 Imaging performed during any type of active treatment (chemotherapy or other medications, radiation therapy, or surgery), including evaluation at the end of planned active treatment Unless otherwise stated in the diagnosis-specific guidelines, imaging for treatment response can be approved after every 2 cycles, which is usually ~6 weeks of therapy for solid tumors and usually ~8 to 12 weeks for CNS tumors
Surveillance	 Imaging performed in individuals who are asymptomatic or have chronic stable symptoms and not receiving any active treatment, even if residual imaging abnormalities are present PET imaging is not supported for surveillance imaging unless specifically stated in elsewhere in the diagnosis-specific guideline sections

Phases of Oncology Imaging	Definition
	All imaging studies completed at the time a recurrence or progression of a known cancer is strongly suspected or documented based on clinical signs or symptoms, laboratory findings, or results of basic imaging studies such as plain radiography or ultrasound
Recurrence	Following documented recurrence of childhood cancer, any studies recommended for initial staging of that cancer type in the diagnosis-specific imaging guideline section should be approved
	 During active treatment for recurrent pediatric cancer, conventional imaging evaluation (CT or MRI, should use the same modality for ongoing monitoring as much as possible) of previously involved areas should be approved according to the treatment response imaging in the diagnosis-specific guideline section Always refer to the diagnosis specific guideline for PET indications in recurrence.

- Brain imaging is performed for signs or symptoms of brain disease
 - MRI Brain without and with contrast (CPT® 70553) is the recommended study for evaluation of suspected or known brain metastases. If a non-contrast CT head shows suspicious lesion, MRI Brain may be obtained to further characterize the lesion
 - CT Head without and with contrast (CPT® 70470) can be approved when MRI is contraindicated or not available, or if there is skull bone involvement
 - Certain malignancies including, but not limited to melanoma, lung cancer and renal cell cancer have indications for brain imaging for asymptomatic individuals
 - If stage IV disease is demonstrated elsewhere or if systemic disease progression is noted, refer to disease specific guidelines
 - Initiation of angiogenesis therapy is not an indication for advanced imaging of the brain in asymptomatic individuals (Avastin/Bevacizumab; <3% risk of bleeding and <1% risk of serious bleeding)

Bone Scan:

- Primarily used for evaluation of bone metastases in individuals with solid malignancies.
- Indications for bone scan in individuals with history of malignancy include bone pain, rising tumor markers, elevated alkaline phosphatase or in individuals with primary bone tumor.
- For evaluation of suspected or known bony metastases, CPT[®] 78306 (Nuclear bone scan whole body), may be approved.

- Radiopharmaceutical Localization scan SPECT (CPT® 78803 or CPT® 78831) or SPECT/CT (CPT® 78830 or CPT® 78832) may be approved as an add-on test for further evaluation of a specific area of interest.
- CPT® codes 78300 (Nuclear bone scan limited), 78305 (Nuclear bone scan multiple areas) or 78315 do not have any indications in oncology nuclear medicine imaging.
- Bone scan supplemented by plain x-rays are the initial imaging modalities for suspected malignant bone pain. For specific imaging indications, see also:
 - ◆ ONC-1.3: Nuclear Medicine (NM) Imaging in Oncology
 - ONC-31.5: Bone (including Vertebral) Metastases
 - ONC-31.6: Spinal Cord Compression
 - ONC-31.7: Carcinoma of Unknown Primary Site
- Delay PET/CT for at least 12 weeks after completion of radiation treatment, unless required sooner for imminent surgical resection.
- PET/CT may be considered prior to biopsy in order to determine a more favorable site for biopsy when a prior biopsy was nondiagnostic or a relatively inaccessible site is contemplated which would require invasive surgical intervention for biopsy attempt.
- PET/CT may be indicated if:
 - Conventional imaging (CT, MRI or bone scan) reveals findings that are inconclusive or negative, with continued suspicion for recurrence
- Unless specified in diagnosis-specific guideline section PET/CT Imaging is NOT indicated for:
 - Infection, inflammation, trauma, post-operative healing, granulomatous disease, rheumatological conditions
 - Concomitantly with separate diagnostic CT studies
 - Conclusive evidence of distant or diffuse metastatic disease on recent conventional imaging studies
 - Metastatic disease in the central nervous system (CNS)
 - Lesions less than 8 mm in size
 - Follow up after localized therapy (i.e. radiofrequency ablation, embolization, stereotactic radiation, etc.)
 - Rare malignancies, due to lack of available evidence regarding the diagnostic accuracy of PET in rare cancers
 - Surveillance
 - Serial monitoring of individuals who are not currently receiving anti-tumor treatment or are receiving maintenance treatment
 - Serial monitoring of FDG avidity until resolution.
 - PET/CT avidity in a residual mass at the end of planned therapy is not an indication for PET/CT imaging during surveillance.
 - Residual mass that has not changed in size since the last conventional imaging does not justify PET imaging

- Please refer to general guidelines section <u>ONC-1.4: PET Imaging in Oncology</u> and <u>PEDONC-1.4: PET Imaging in Pediatric Oncology</u> for further guidance regarding PET. Those guidelines should be applied with regard to radiotracer coverage.
- Please refer to general guidelines in <u>ONC-1.5: Unlisted Procedure Codes in Oncology</u> for unlisted procedures in pediatric oncology.

Clinical Trials

- Similar to investigational and experimental studies, clinical trial imaging requests will be considered to determine whether they meet Health Plan coverage and eviCore's evidence-based guidelines.
- Imaging studies which are inconsistent with established clinical standards, or are requested for data collection and not used in direct clinical management are not supported.

PEDONC-1.1: Age Considerations

- The majority of malignancies occurring in the pediatric population are different diagnoses than those occurring in the adult population
- For those diseases which occur in both pediatric and adult populations, minor differences may exist in management between pediatric and adult medical oncologists due to the following:
 - Age of the individual
 - Comorbidities
 - Differences in disease natural history between children and adults

AGE APPROPRIATE GUIDELINES		
Age of Individual	f Individual Appropriate Imaging Guidelines	
≥18 years old at initial diagnosis	 General Oncology Imaging Guidelines, except where directed otherwise by a specific guideline section 	
<18 years old at initial diagnosis	 Pediatric Oncology Imaging Guidelines, except where directed otherwise by a specific guideline section 	
15 to 39 years old at initial diagnosis (defined as Adolescent and Young Adult (AYA)	When unique guidelines for a specific cancer type exist only in either Oncology or Pediatric Oncology, AYA individuals should be imaged according to the guideline section for their specific cancer type, regardless of the individual's age	
oncology individuals)	When unique guidelines for a specific cancer type exist in both Oncology and Pediatric Oncology, AYA individuals should be imaged according to the age rule in the previous bullet	

PEDONC-1.2: Appropriate Clinical Evaluations

- The majority of pediatric oncology imaging indications are listed in the diagnosisspecific guideline sections
 - Rare malignancies and other circumstances not specifically addressed elsewhere in the Pediatric Oncology guidelines, the following general principles apply:
 - Routine imaging of brain, spine, neck, chest, abdomen, pelvis, bones, or other body areas is not indicated in the absence of:
 - Localizing symptoms or
 - Abnormalities on plain radiography or ultrasound
- The overwhelming majority of pediatric oncology individuals treated in the United States will be enrolled on or treated according to recent Children's Oncology Group (COG) protocols
 - COG is a National Cancer Institute (NCI) supported clinical trials group
 - These imaging guidelines are consistent with evaluations recommended by COG protocols commonly used for direct individual care (whether formally enrolled on study or not)
- For individuals enrolled on a COG study, imaging recommended by COG protocols should generally be approved unless the imaging is being performed solely to address a study objective and would not be indicated in usual clinical care

Phases of Pediatric Oncology Imaging:

- Pediatric malignancies, in general, behave more aggressively than adult cancers, and the time from initial suspicion of cancer to specific therapy initiation can be measured in hours to days for most pediatric cancers
- It is recommended that children with pediatric solid tumors undergo CT evaluation of the chest prior to general anesthesia for biopsy or resection due to the risk of postoperative atelectasis mimicking pulmonary metastasis resulting in inaccurate staging and/or delay in therapy initiation
- Unlike adult cancers, in most pediatric cancers surveillance does not begin until all planned multimodal therapy is completed
- Pediatric cancers where surgical resection is considered curative are listed in the diagnosis-specific guideline sections
- Certain tumor types do not require surveillance with advanced imaging as individual outcomes following relapse are not improved by surveillance imaging. See diagnosis-specific guideline sections for details
- Imaging may be indicated more frequently than recommended by guidelines with clinical documentation that the imaging results are likely to result in a treatment change for the individual, including a change from active treatment to surveillance

Phases of Oncology Imaging	Definition	
Screening	 Imaging requested for individuals at increased risk for a particular cancer in the absence of known clinical signs or symptoms Screening using advancing imaging is only supported for conditions listed in PEDONC-2: Screening Imaging in Cancer Predisposition Syndromes 	
Suspected/Initial Staging	 All imaging studies requested from the time cancer is first clinically suspected until the initiation of specific treatment CT Chest prior to anesthesia for biopsy or resection of solid tumors and CTs of other involved body areas are generally indicated and should be performed concurrently Metastatic CNS imaging and nuclear medicine imaging are generally deferred until after a histologic diagnosis is made, unless otherwise indicated by diagnosis-specific guideline 	
Treatment Response	 Imaging performed during any type of active treatment (chemotherapy or other medications, radiation therapy, or surgery), including evaluation at the end of planned active treatment Unless otherwise stated in the diagnosis-specific guidelines, imaging for treatment response can be approved after every 2 cycles, which is usually ~6 weeks of therapy for solid tumors and usually ~8 to 12 weeks for CNS tumors 	
Surveillance	 Imaging performed in individuals who are asymptomatic or have chronic stable symptoms and not receiving any active treatment, even if residual imaging abnormalities are present PET imaging is not supported for surveillance imaging unless specifically stated in elsewhere in the diagnosis-specific guideline sections 	

Phases of Oncology Imaging	Definition
Recurrence	 All imaging studies completed at the time a recurrence or progression of a known cancer is strongly suspected or documented based on clinical signs or symptoms, laboratory findings, or results of basic imaging studies such as plain radiography or ultrasound Following documented recurrence of childhood cancer, any studies recommended for initial staging of that cancer type in the diagnosis-specific imaging guideline section should be approved During active treatment for recurrent pediatric cancer, conventional imaging evaluation (CT or MRI, should use the same modality for ongoing monitoring as much as possible) of previously involved areas should be approved according to the treatment response imaging in the diagnosis-specific guideline section Always refer to the diagnosis specific guideline for PET indications in recurrence.

<u>Cardiac Function Assessment in Pediatric Oncology During Active Treatment</u>:

Indication	Imaging Study
 Evaluation of cardiac function prior to cardiotoxic chemotherapy, at the discretion of the treating pediatric oncologist based on: Cumulative cardiotoxic therapy received to date Individual's age and gender Most recent echocardiogram results New or worsening cardiac symptoms 	Echocardiography (CPT® 93306, CPT® 93307, or CPT® 93308)
 For either of the following: Echocardiography yielded a borderline shortening fraction (<30%) and additional left ventricular function data are necessary to make a chemotherapy decision OR Echocardiography windowing is suboptimal due to body habitus or tumor location 	 Multi-gated acquisition (MUGA, CPT[®] 78472) blood pool nuclear medicine scanning

<u>Immunosuppression During Pediatric Cancer Therapy and Imaging</u> Ramifications:

- Individuals may be severely immunocompromised during active chemotherapy treatment and any conventional imaging request to evaluate for infectious complications during this time frame should be approved immediately
 - Imaging requests for infectious disease concerns for all individuals with absolute neutrophil count (ANC) <500 or
 - Inconclusive findings on chest x-ray or US at any ANC during active treatment should be approved as requested
 - Individuals may have therapy-induced hypogammaglobulinemia which requires supplemental intravenous immune globulin (IVIG) during maintenance therapy. These individuals receiving supplemental IVIG should be treated similarly to individuals with ANC <500 with regards to imaging for infectious disease
- Some individuals are treated with very intensive chemotherapy regimens (including autologous stem cell transplantation) and spend the majority of their chemotherapy treatment phase in the hospital. See: <u>ONC-29: Hematopoietic Stem Cell Transplantation</u>.
- Due to the high risk of invasive infections, frequent CT may be indicated to evaluate known sites of invasive fungal infection, and in general these should be approved as requested
 - Surveillance imaging of asymptomatic individuals to detect invasive fungal infection has not been shown to impact individual outcomes
 - Imaging requests are indicated when acute clinical decisions will be made based on the imaging

Hematopoietic Stem Cell Transplant (HSCT) in Pediatric Oncology:

- Transplantation of hematopoietic stem cells from bone marrow, peripheral blood, or cord blood is commonly used in the following clinical situations:
 - High risk or recurrent leukemia (allogeneic)
 - Recurrent lymphoma (allogeneic or autologous)
 - Hemophagocytic lymphohistiocytosis (allogeneic)
 - High risk sickle cell disease (allogeneic)
 - High risk neuroblastoma (autologous)
 - High risk CNS tumors (autologous)
 - Recurrent Ewing sarcoma family of tumors (autologous, rarely allogeneic)
- ➤ Imaging considerations for HSCT should follow guidelines in: <u>ONC-29:</u> Hematopoietic Stem Cell Transplantation.

PEDONC-1.3: Modality General Considerations

Plain radiography

- Chest x-ray (CXR) can provide a prompt means to evaluate primary intrathoracic tumors and continues to be the initial imaging study recommended to detect complications, such as suspected infection, in symptomatic individuals undergoing treatment.
- CXR continues to be the initial imaging study recommended for pulmonary surveillance for some pediatric cancers. See diagnosis-specific guideline sections for details.
- Plain radiography continues to be the initial imaging study recommended for evaluation of lesions involving the appendicular skeleton, both during and after completion of treatment. See diagnosis-specific guideline sections for details.
- Plain abdominal radiographs have largely been replaced by ultrasound, CT, or MRI.

Ultrasound

- Ultrasound is not widely used in pediatric oncology for staging, but is frequently used for surveillance in individuals who have successfully treated (primarily abdominal or pelvic) tumors with little or no residual disease.
- See diagnosis-specific guideline sections for details.

> CT

- CT with contrast is the imaging study of choice in pediatric individuals with lymphomas or solid tumors of the neck, thorax, abdomen, and/or pelvis
 - If CT contrast use is contraindicated due to allergy or impaired renal function, either CT without contrast or MRI with and without contrast may be substituted at the discretion of the ordering physician.

➤ MRI

- MRI without and with contrast is the study of choice for CNS tumors and musculoskeletal tumors
 - If MRI without contrast is contraindicated due to allergy or impaired renal function, MRI without contrast may be substituted at the discretion of the ordering physician
- Due to the length of time for image acquisition and the need for stillness, anesthesia is required for almost all infants and young children (age <7 years), as well as older children with delays in development or maturity. In this population, MRI imaging sessions should be planned with a goal of avoiding a short-interval repeat anesthesia exposure due to insufficient information using the following considerations:</p>
 - MRI should always be performed without and with contrast unless there is a specific contraindication to gadolinium use since the individual already has intravenous access for anesthesia
 - Recent evidence-based literature demonstrates the potential for gadolinium deposition in various organs including the brain, after the use of MRI contrast
 - The U.S. Food and Drug Administration (FDA) has noted that there is currently no evidence to suggest that gadolinium retention in the brain is

- harmful and restricting gadolinium-based contrast agents (GBCAs) use is not warranted at this time
- It has been recommended that GBCA use should be limited to circumstances in which additional information provided by the contrast agent is necessary and the necessity of repetitive MRIs with GBCAs should be assessed
- If requesting clinicians indicate that a non-contrast study is being requested due to concerns regarding the use of gadolinium, the exam can be approved
- If multiple body areas are supported by eviCore Guidelines for the clinical condition being evaluated, MRI of all necessary body areas should be obtained concurrently in the same anesthesia session

Nuclear Medicine

- General PET imaging considerations can be found in <u>PEDONC-1.4: PET Imaging in Pediatric Oncology</u>
- Bone scan is frequently used for evaluation of bone metastases in pediatric oncology during initial treatment, treatment response, and surveillance
 CPT® 78315 has no specific indications for evaluation of malignant disease
- ◆ ¹²³I-metaiodobenzylguanidine (MIBG) scintigraphy is the preferred metabolic imaging for neuroblastoma and is positive in 90 to 95% of neuroblastomas. MIBG is also used for evaluation of pheochromocytomas, paragangliomas, ganglioneuromas, and ganglioneuroblatomas, PET/CT indications are provided in the relevant sections.

Study Type	Coding
Bone scan	 ANY of the following codes can be approved: CPT® 78300 CPT® 78305 CPT® 78306 CPT® 78803, 78830, or 78832 May be approved alone or in combination with: CPT® 78305 CPT® 78306
¹²³ I-metaiodobenzylguanidine (MIBG) scintigraphy	 ANY one of the following codes can be approved: CPT® 78801 CPT® 78802 CPT® 78804 ANY one of the following codes may also be approved, individual or in combination with CPT® 78801,78802 or 78804: CPT® 78803 CPT® 78830 CPT® 78831 CPT® 78832 CPT® 78800 may be approved for KNOWN neuroblastoma when only a single site follow up is desired, but is not sufficient for the initial workup of suspected disease
Octreotide scan	Same coding as MIBG
Gallium scan	Same coding as MIBG

PEDONC-1.4: PET Imaging in Pediatric Oncology

Throughout these guidelines, the term "PET" refers specifically to ¹⁸F-FDG-PET imaging and also applies to PET/CT fusion studies.

- PET imaging in pediatric oncology should use PET/CT fusion imaging (CPT® 78815 or CPT® 78816)
- ➤ The decision whether to use skull base to mid-femur ("eyes to thighs") procedure code for PET (CPT® 78815) or Whole body PET (CPT® 78816) is addressed in the diagnosis-specific guideline sections
- PET imaging in oncology should use PET/CT fusion imaging (CPT® 78815 or CPT® 78816)
- PET/MRI is generally not supported by eviCore for a vast majority of oncologic conditions due to lack of standardization in imaging technique and interpretation. However, it may be approved in certain pediatric oncologic conditions when all of the following criteria are met:
 - The individual meets guideline criteria for PET/CT AND
 - PET/CT is **not** available at the treating institution <u>AND</u>
 - The provider requests PET/MRI in lieu of PET/CT
 - When the above criteria are met, PET/MRI may be approved using the code combination of PET Whole Body (CPT® 78813) and MRI Unlisted (CPT® 76498). All other methods of reporting PET/MRI are inappropriate.
 - When clinically appropriate, diagnostic MRI codes may be approved at the same time as the PET/MRI code combination.
- Unbundling PET/CT imaging into separate PET (such as CPT® 78812 or CPT® 78813) and diagnostic CT codes is otherwise not supported.
- PET imaging is not reliable for the detection of anatomic lesions smaller than 8 mm in size.
- Delay PET/CT for at least 12 weeks after completion of radiation treatment, unless required sooner for imminent surgical resection.
- ➤ PET imaging using isotopes other than ¹⁸F-FDG, ⁶⁸Ga-DOTATATE, or ⁶⁸Ga-DOTATOC is considered investigational at this time. Please see the table below for the most commonly used isotopes and their corresponding codes
 - Covered:
 - 18F-FDG
 - 68Ga-DOTATATE (NETSPOT®) for low grade neuroendocrine tumors
 - 68Ga-DOTATOC for low grade neuroendocrine tumors Not covered:
 - PET/CT imaging using isotopes other than those specified above

CPT/ HCPCS Code	Code Description	Brand or common name	FDA-approved?	Code reviewed by eviCore for Cigna?
A9552	fluorine-18 (F-18) fluorodeoxyglucose (FDG), diagnostic, per study dose, up to 45 millicuries	FDG	Yes, to assess abnormal glucose metabolism	No
A9587	Gallium GA-68, dotatate, diagnostic, 0.1 millicurie	NETSPOT®	Yes, for localization of somatostatin receptor positive neuroendocrine tumors in adult and pediatric population	No
C9067	⁶⁸ Ga Gallium-DOTA- TOC	N/A	Yes, for somatostatin receptor (SSTR) positive gastroenteropancreatic neuroendocrine tumors	No

- PET has not been shown to be diagnostically useful in all forms of childhood cancer. PET is supported for pediatric malignancies with significant published evidence regarding its diagnostic accuracy and importance in accurately directing individual care decisions. See diagnosis-specific guideline sections for details
- PET imaging is not specific to cancer, and has a high rate of false positivity. Inflammation, infection (especially granulomatous), trauma, and post-operative healing may show high levels of FDG update and be false-positive for malignant lesions
- PET for rare malignancies not specifically addressed by eviCore guidelines is generally not indicated, due to lack of available evidence regarding diagnostic accuracy of PET in the majority of rare cancers. Conventional imaging studies should be used for initial staging and treatment response for these diagnoses
- PET can be approved if all of the following apply:
 - Conventional imaging (CT, MRI, US, plain film) reveals findings that are equivocal or suspicious
 - No other specific metabolic imaging (MIBG, octreotide, technetium, etc.) is appropriate for the cancer type
 - The submitted clinical information describes a specific decision regarding the individual's care that will be made based on the PET results
- PET imaging for surveillance imaging only when specifically stated elsewhere in the diagnosis-specific guideline sections

- Unless otherwise specified for a specific cancer type, once PET has been documented to be negative for a given individual's cancer or all PET-avid disease has been surgically resected, PET should not be used for continued disease monitoring or surveillance unless one of the following applies:
 - Conventional imaging (CT, MRI, US, plain film) reveals findings that are inconclusive or suspicious for recurrence
 - Residual mass that has not changed in size since the last conventional imaging does **not** justify PET imaging
 - PET avidity in a residual mass at the end of planned therapy is not an indication for PET imaging during surveillance
 - Very rare circumstances where tumor markers or obvious clinical symptoms show strong evidence suggesting recurrence and PET would replace conventional imaging modalities
 - The individual is undergoing salvage treatment for a recurrent solid tumor with residual measurable disease on conventional imaging and confirmed repeat negative PET imaging will allow the individual to transition from active treatment to surveillance

PEDONC-1.5: Diagnostic Radiation Exposure in Pediatric Oncology

- Young children are presumed to be at increased risk for malignancy from diagnostic radiation exposure, most commonly from CT and nuclear medicine imaging. They are more sensitive to radiation than adults and generally live longer after receiving radiation doses from medical procedures, resulting in a larger number of years during which to manifest a cancer.
- Because of this presumed increased risk in young children, requests to substitute MRI without and with contrast for CT with contrast to avoid radiation exposure if ALL of the following criteria apply:
 - The individual is presently a young child and the ordering physician has documented the reason for MRI, rather than CT, is to avoid radiation exposure.
 - The disease-specific guidelines do not list CT as superior to MRI for the current disease and time point, meaning the MRI will provide equivalent or superior information relative to CT.
 - The request is for a body area other than chest as MRI is substantially inferior to CT for detection of small pulmonary metastases.
- The guidelines listed in this section for certain specific indications are not intended to be all-inclusive; clinical judgment remains paramount and variance from these guidelines may be appropriate and warranted for specific clinical situations.

<u>PEDONC-2.1: Screening Imaging in Cancer Predisposition Syndromes</u> – General Considerations

- This section is intended to give guidance for screening imaging prior to diagnosis with a specific malignancy. Once an individual with a cancer predisposition syndrome has been diagnosed with a malignant disease, future imaging decisions should be guided by the appropriate disease-specific guidelines except as explicitly stated elsewhere in this section.
- This section's guidelines are limited to cancer predisposition syndromes with screening imaging considerations. Syndromes requiring only clinical or laboratory screening are not discussed here.
- In general, a recent (within 60 days) detailed history and physical examination and appropriate laboratory studies should be performed prior to considering advanced imaging, unless the individual is undergoing guideline-supported scheduled screening evaluation identified in this section.
- Where MRI is indicated in these guidelines, CT may be approved only if MRI is contraindicated, given the risk of radiation exposure in these syndromes.
- Many of these cancer predisposition syndromes also affect adults as survival continues to improve for these individuals.
 - Adults with syndromes covered in this section may follow these imaging guidelines except where contradicted by specific statements in the general imaging guideline.

PEDONC-2.2: Li-Fraumeni Syndrome (LFS)

The following imaging studies should be considered appropriate in individuals with LFS:

Indication	Imaging Study
All individuals	 BOTH of the following, annually: MRI Brain without and with contrast (CPT® 70553) Whole-body MRI (WBMRI CPT® 76498) CPT® 76498 is the only approvable code for whole-body MRI at this time. Every 3 months from birth to age 18: Abdominal (CPT® 76700) and pelvic (CPT® 76856) ultrasound Beginning at age 20: Annual MRI Breast (CPT® 77049), alternating every 6 months with breast ultrasound, in addition to the previously noted annual MRI studies.
Documented signs or symptoms suggestive of possible malignancy	 Targeted MRI without and with contrast of the involved body area(s)

Background and Supporting Information

- ➤ LFS syndrome inherited in an autosomal dominant manner (50% risk to offspring) associated with germline mutations in *TP53* resulted in an increased susceptibility to a variety of cancers.
 - Eighty percent of individuals will have germline *TP53* mutation:
 - Tumor-specific TP53 mutations are much more common than germline TP53 mutations and are not associated with an increased risk for subsequent cancers.
 - If TP53-negative, formal diagnosis of LFS should be assigned by a physician with significant training and/or experience in LFS (most commonly a geneticist or oncologist) based on specified clinical criteria prior to beginning a screening imaging program.
 - ◆ TP53 mutations may be present in 50 to 80% of pediatric adrenocortical carcinoma, 10% of pediatric rhabdomyosarcoma, and 10% of pediatric osteosarcoma.
- Individuals with LFS have an increased sensitivity to ionizing radiation, so screening strategies resulting in significant radiation exposure are not appropriate (CT and nuclear medicine).
- When a specific malignancy is suspected, the individual should be imaged according to the eviCore imaging guideline specific to the suspected cancer type
- Annual complete detailed physical examinations, complete blood counts, and urinalyses form the backbone of LFS cancer screening.

PEDONC-2.3: Neurofibromatosis 1 and 2 (NF1 and NF2)

The following imaging studies should be considered appropriate in individuals with NF1:

	Indication		Imaging Study	
>	Clarification of the diagnosis of NF1 if evaluation by a physician with significant training and/or experience in neurofibromatosis is inconclusive Most commonly a neurologist, geneticist, ophthalmologist, or oncologist	>	One-time MRI Brain (CPT® 70553) and Orbits (CPT® 70543) without and with contrast	
>	New or worsening neurological or visual symptoms	>	MRI Brain (CPT® 70553) and Orbits (CPT® 70543) without and with contrast	
>	 Clinical symptoms suggestive of change in a known plexiform neurofibroma Examples include: pain, rapid growth, and neurologic dysfunction 	>	MRI without and with contrast	
>	Clinical symptoms concerning for malignant transformation of a known plexiform neurofibroma, and ALL of the following are met: ◆ Recent MRI is inconclusive regarding transformation or progression ◆ Negative PET will result in a decision to avoid biopsy in a difficult or morbid location	>	PET/CT (CPT® 78815 or CPT® 78816)	
>	Baseline tumor burden at age 16 or older (one-time imaging)	>	WBMBRI (CPT® 76498)	
>	New soft tissue mass(es)	>	See: MS-10.1 in the Musculoskeletal Imaging Guidelines or PEDMS-3.2 in the Pediatric Musculoskeletal Imaging Guidelines depending on the individual's age at the time the mass is discovered. Plain x-ray or ultrasound is not required prior to advanced imaging in these individuals.	
>	New bone mass(es)	>	See: PEDONC-9.1: Bone Tumors	
>	Documented optic pathway gliomas	>	See: PEDONC-4.2: Intracranial Low Grade Gliomas	
>	Known plexiform neurofibromas	>	 MRI without and with contrast of a known body area containing a neurofibroma is indicated for any of the following: Every 3 months for treatment response in individuals receiving active treatment New or worsening clinical symptoms suggesting progression Preoperative planning 	

Biopsy-proven MPNST in individuals with	> See: PEDONC-8.3: Non-
known NF-1 or NF-2	Rhabdomyosarcoma Soft Tissue
	Sarcomas (NRSTS)

NF1:

- Common syndrome inherited in an autosomal dominant manner (50% risk to offspring) affecting 1 in 2500 people. The diagnosis is commonly made based on established clinical criteria including café-au-lait spots, lisch nodules of the iris, axillary freckling, family history, and the presence of NF- associated tumors.
- The majority of tumors are benign in nature, but malignant degeneration can occur. The most frequent neoplasms associated with NF1 in children are malignant peripheral nerve sheath tumor (MPNST), glioma, pheochromocytoma, and leukemia.
- NF1-affected persons have increased sensitivity to ionizing radiation, so CT and nuclear medicine imaging are not appropriate screening or surveillance studies for these individuals.
- Annual ophthalmology evaluation is strongly recommended beginning at the time of diagnosis of NF1 to evaluate for optic pathway abnormalities:
 - Screening MRIs Brain (CPT® 70553) and Orbits (CPT® 70543) for asymptomatic individuals are **not** generally recommended due to the ~60% rate of unidentified bright objects (UBOs, T2-weighted signal abnormalities) which mostly disappear by age 30
 - Routine follow up imaging of UBOs is not warranted in the absence of acute symptoms suggesting new or worsening intracranial disease
- Individuals with NF1 are at increased risk for plexiform neurofibromas (PN) and malignant peripheral nerve sheath tumors (MPNST—a high grade sarcoma)
 - Screening imaging of asymptomatic individuals for these tumors is not supported by evidence. PET imaging is not supported for PN surveillance in asymptomatic individuals at this time as the positive predictive value is only 60 to 65% even in symptomatic individuals
- Although PET imaging has a positive predictive value of only 61 to 63% in NF1 individuals with suspected transformation to MPNST, the negative predictive value is high (96 to 99%)
 - Considerations for PET/CT coding and indications/coding for PET/MRI are found in <u>PEDONC-1.4: PET Imaging in Pediatric Oncology</u>
 - Repeat PET studies are not indicated due to the poor positive predictive value in this setting
- 2017 AACR recommendations support a single baseline Whole-Body MRI to assess tumor burden in late adolescence or young adulthood. Further imaging should be based on focused MRI for symptomatic changes or pre-operative planning, and further surveillance WBMRI are not supported.

The following imaging studies should be considered appropriate in individuals with NF2:

Indication	Imaging Study			
All individuals, beginning at age 10 years	 Annual MRI Brain without and with contrast (CPT[®] 70553) 			
 All individuals without a history of spinal tumors, beginning at age 10 years 	 MRI Spine without and with contrast (Cervical-CPT[®] 72156, Thoracic-CPT[®] 72157, Lumbar-CPT[®] 72158) every 3 years 			
All individuals with a history of spinal tumors	Annual MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)			
 Clinical symptoms of intracranial mass or vestibular disease 	 MRI Brain without and with contrast (CPT® 70553) 			
 Any of the following: Clinical symptoms suggestive of new or progressive spinal or paraspinal tumors, including uncomplicated back pain or radiculopathy Recent diagnosis with a meningioma or vestibular schwannoma 	MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)			
 Surveillance for progression of unresected tumors in individuals with known vestibular schwannoma 	Annual MRI Brain without and with contrast (CPT® 70553)			
 Known vestibular schwannomas and any of the following: New or worsening clinical symptoms including hearing loss Preoperative planning 	MRI Brain without and with contrast (CPT® 70553)			
Known meningioma	See: ONC-2.8: Meningiomas in the Oncology Imaging Guidelines			
Known ependymoma	> See: PEDONC-4.8: Ependymoma			

Background and Supporting Information

NF2:

➤ NF2 is substantially less common than NF1. It is inherited in an autosomal dominant manner (50% risk to offspring) affecting ~1 in 25000 people. NF2 is associated with increased risk for Meningiomas (50% of affected individuals), vestibular schwannomas, and spinal tumors (75% of affected individuals).

PEDONC-2.4: Beckwith-Wiedemann Syndrome (BWS)

The following imaging studies should be considered appropriate in individuals with BWS:

Indication	Imaging Study
 All individuals, from birth to the 8th birthday 	 Abdominal ultrasound (CPT[®] 76700) every 3 months
Purely cystic adrenal mass found on screening ultrasound	Continue screening ultrasound (CPT® 76700 or 76705) every 3 months without additional imaging (i.e. advanced imaging is not supported for a purely cystic adrenal mass)
 Solid or mixed adrenal mass found on screening ultrasound AND: Individual age 0 to 5 months, and Mass 0 to 3 cm in diameter 	MIBG imaging (See: <u>PEDONC-1.3</u> for coding) and either CT or MRI Abdomen (contrast as requested)
 Solid or mixed adrenal mass found on screening ultrasound AND: Individual age 0 to 5 months, and Mass > 3 cm in diameter 	MIBG imaging (See: <u>PEDONC-1.3</u> for coding) and MRI Abdomen (contrast as requested)
 Solid or mixed adrenal masses on screening ultrasound AND: Individual age 6 months or greater 	 MIBG imaging (See: <u>PEDONC-1.3</u> for coding) prior to biopsy or resection If no evidence of malignancy on biopsy or resection, resume screening abdominal ultrasound every 3 months
 Solid or mixed adrenal masses on screening ultrasound AND: No evidence of malignancy based on MIBG, CT or MRI, Urine HVA/VMA, and serum ACTH 	Repeat abdominal ultrasound (CPT [®] 76700 or 76705) every 6 weeks for 2 years
Known renal tumors	See: <u>PEDONC-7: Pediatric Renal</u> <u>Tumors</u>
Known hepatoblastoma	See: <u>PEDONC-11.2:</u> <u>Hepatoblastoma</u>
Known neuroblastoma	> See: PEDONC-6: Neuroblastoma
Known adrenocortical carcinoma	See: <u>PEDONC-14: Pediatric</u> <u>Adrenocortical Carcinoma</u>
Known pheochromocytoma	See: ONC-15: Neuroendocrine Cancers and Adrenal Tumors in the Oncology Imaging Guidelines

- Inherited syndrome characterized by macroglossia, hemihypertrophy, macrosomia, organomegaly, and neonatal hypoglycemia. Individuals with isolated hemihypertrophy are also imaged according to this guideline.
- Caused by mutation at chromosome 11p15, affected children are predisposed to Wilms tumor, hepatoblastoma, rhabdomyosarcoma, and adrenal tumors.

PEDONC-2.5: Denys-Drash Syndrome (DDS)

The following imaging studies should be considered appropriate in individuals with DDS:

Indication	Imaging Study
All individuals, from birth to the 8th	Abdominal ultrasound (CPT® 76700)
birthday	every 3 months
Known renal tumors	> See: PEDONC-7: Pediatric Renal
	<u>Tumors</u>

Background and Supporting Information

Characterized by pseudohermaphroditism, early renal failure, and >90% risk of Wilms tumor development in each kidney. Associated with mutations at 11p13, risk of renal failure after detection of symptomatic Wilms tumor is 62%, so early detection may allow for renal-sparing surgical approaches

PEDONC-2.6: Wilms Tumor-Aniridia-Growth Retardation (WAGR)

The following imaging studies should be considered appropriate in individuals with WAGR:

Indication	Imaging Study
All individuals, from birth to the 8th birthday	Abdominal ultrasound (CPT® 76700) every 3 months
Known renal tumors	See: PEDONC-7: Pediatric Renal Tumors

Background and Supporting Information

Named for the components of the disorder, it is associated with mutations at 11p13. As the name suggests, individuals are predisposed to Wilms tumor, with 57% of individuals in one cohort developing Wilms tumor. Risk of renal failure after detection of symptomatic Wilms tumor is 38%, so early detection may allow for renal-sparing surgical approaches

<u>PEDONC-2.7: Familial Adenomatous Polyposis (FAP) and Related</u> <u>Conditions</u>

Individuals with Lynch, Gardner, and Turcot syndromes should also be imaged according to these guidelines.

The following imaging studies should be considered appropriate in individuals with FAP and related conditions:

For colonoscopy and endoscopy guidance for those with FAP and related conditions, See: <u>EGD 1.16</u>, <u>CAPEND-5</u>, <u>or COLON-17</u>: <u>Genetic Syndromes</u> for the endoscopic management of polyposis syndromes

onaccopic management of polypoole cynaccines			
Indication	on	Imaging Study	
All individuals, from be birthday	birth to the 6 th	 Abdominal ultrasound (CPT[®] 76700) every 3 months 	
All individuals, begin years	ning at age 12	► Annual thyroid ultrasound (CPT® 76536)	
All individuals, begin years	ning at age 30	 Annual pelvic ultrasound (CPT[®] 76856) 	
Family history of des	smoid tumors	annually for life after age 6	
 Individuals with Spig IV or if duodenectom planned See: <u>EGD-1.16: (Syndromes</u> for a information regarstaging. 	ny is being Genetic additional	MR Enterography (MRI Abdomen without and with contrast, CPT® 74183 and MRI Pelvis without and with contrast, CPT® 72197)	
Known colorectal tur	nors	See: ONC-16: Colorectal Cancer in the Oncology Imaging Guidelines	
Known desmoid tum	ors	See: PEDONC-8.3: Non- Rhabdomyosarcoma Soft Tissue Sarcomas (NRSTS)	

Background and Supporting Information

Inherited in an autosomal dominant manner (50% risk to offspring), it is also known as Adenomatous Polyposis Coli (APC). It is associated with the development of thousands of colonic polyps by age 20 and >90% risk of colorectal carcinoma. Prophylactic total colectomy is recommended by age 20 for most individuals. FAP is also associated with hepatoblastoma, tumors of the pancreas and small bowel, medulloblastoma, and thyroid cancer.

PEDONC-2.8: Multiple Endocrine Neoplasias (MEN)

The following imaging studies should be considered appropriate in individuals with MEN1:

Indication	Imaging Study
All individuals, beginning at age 5 years	 Annual MRI Brain without and with contrast (CPT® 70553) Annual MRI Abdomen without and with contrast (CPT® 74183), CT Abdomen with contrast (CPT® 74160), or ultrasound (CPT® 76700) Annual Octreotide study (See: PEDONC-1.3 for coding)
 All individuals, beginning at age 15 years 	 Annual MRI Chest without and with contrast (CPT® 71552) or CT Chest with contrast (CPT® 71260)
Known thyroid cancer	See: <u>ONC-6: Thyroid Cancer</u> in the Oncology Imaging Guidelines
Known pheochromocytoma	 See: ONC-15: Neuroendocrine Cancers and Adrenal Tumors in the Oncology Imaging Guidelines
The following imaging studies should be considered appropriate in individuals with MEN2a and MEN2b:Indication	Imaging Study
All individuals, beginning at age 5 years	 MRI Abdomen without and with contrast (CPT[®] 74183) can be approved every 3 years
 One of the following: Elevated catecholamines Inconclusive adrenal mass on MRI 	 ONE of the following: Octreotide study (See: PEDONC-1.3 for coding) Adrenal Nuclear Imaging (CPT® 78075)
Known pheochromocytoma	 See: ONC-15: Neuroendocrine Cancers and Adrenal Tumors in the Oncology Imaging Guidelines

- Inherited in an autosomal dominant manner (50% risk to offspring).
- MEN1 is characterized by parathyroid, pancreatic islet cell, and pituitary gland tumors (3 P's), as well as carcinoid tumors in the chest and abdomen, and 28% of individuals will develop at least one tumor by age 15.
- MEN2a is characterized by medullary thyroid carcinoma, parathyroid adenomas, and pheochromocytomas.
- ➤ MEN2b is characterized by ganglioneuromas of the GI tract and skeletal abnormalities presenting in infancy.
- Recommended cancer screening includes:
 - MEN2a and MEN2b: Annual measurement of catecholamines for pheochromocytoma screening

PEDONC-2.9: Tuberous Sclerosis Complex (TSC)

➤ Abdominal MRI (CPT® 74183) may be approved for women of childbearing age planning pregnancy.

The following imaging studies should be considered appropriate in individuals with TSC:

Indication	Imaging Study
All individuals, at the time of suspected diagnosis until age 25 years	 Annual Brain MRI without and with contrast (CPT[®] 70553)
All individuals at diagnosis	 Single baseline MRI Abdomen without and with contrast (CPT® 74183)
If no renal lesions seen on baseline MRI Abdomen	 From diagnosis through age 11: Annual Renal US (CPT® 76770) Age 12 (or 10 years earlier than the youngest family member with renal cell carcinoma, whichever comes earlier): MRI Abdomen without and with contrast (CPT® 74183) every 3 years in lieu of ultrasound
 For documented renal lesions on baseline MRI Abdomen or any ultrasound 	MRI Abdomen without and with contrast (CPT® 74183) annually
All individuals, beginning at age 18 years	 CT Chest without contrast (CPT[®] 71250) every 5 years
All individuals, for cardiac screening or follow up of known cardiac disease	See: PEDCD-8.2: Initial Transthoracic Echocardiography (TTE) Indications and PEDCD-8.3: Repeat Transthoracic Echocardiography Indications in the Pediatric Cardiology Imaging Guidelines
Individuals with documented abnormalities on baseline CT Chest	 Additional CT Chest without contrast or with contrast (CPT[®] 71250 or CPT[®] 71260) may be approved every 1 year
 Any of the following: New pulmonary symptoms Worsening pulmonary function testing 	CT Chest without contrast (CPT® 71250)
Known SEGA tumors	See: PEDONC-4.2: Intracranial Low Grade Gliomas (LGG)
Known renal cell carcinoma	See: PEDONC-7.4: Pediatric Renal Cell Carcinoma (RCC)

- ➤ Inherited in an autosomal dominant manner (50% risk to offspring), affecting ~1 in 6000 individuals, it is associated with benign tumors, hypopigmented skin macules (ash leaf spots), pulmonary lymphangioleiomyomatosis, developmental delay, and epilepsy
- Malignancies associated with this syndrome include:
 - Subependymal giant cell astrocytomas (SEGA tumors)
 - Historically, early surgery was important to reduce morbidity related to these tumors
 - More recently, everolimus has been successfully used to treat these tumors without surgery, and early detection remains an important feature for success
 - Renal cell carcinoma
 - Cardiac rhabdomyosarcoma
 - Pulmonary lymphangioleiomyomatosis
- Recommended cancer screening includes:
 - Ophthalmologic and dermatologic evaluation annually

PEDONC-2.10: Von Hippel-Lindau Syndrome (VHL)

The following imaging studies should be considered appropriate in individuals with VHL:

	Haiviadais With VIIE.			
	Indication	Imaging Study		
>	All individuals, beginning at age 8 years	MRI Brain without and with contrast (CPT® 70553) and MRI Spine without and with contrast (Cervical-CPT® 72156), Thoracic-CPT® 72157, and Lumbar-CPT® 72158) every 2 years		
>	Individuals with frequent ear infections, prior to age 8	One-time MRI Brain without and with contrast (CPT [®] 70553)		
>	All individuals, beginning at age 5 years	➤ Annual Abdominal US (CPT® 76700)		
>	All individuals, beginning at age 12 years	MRI Abdomen without and with contrast (CPT® 74183) every 2 years		
>	ONE of the following: ◆ Elevated catecholamines • Inconclusive adrenal mass on MRI	Octreotide study (CPT® 78800, CPT® 78801, CPT® 78802, CPT® 78803, or CPT® 78804) or Adrenal Nuclear imaging (CPT® 78075)		
>	Individuals with known hemangioblastoma anywhere in the body (based on imaging) that has not been resected	 Both of the following, every 1 year: MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156), Thoracic-CPT® 72157, and Lumbar-CPT® 72158) 		
>	Known hemangioblastoma that has not been resected and new or worsening symptoms	 MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156), Thoracic-CPT® 72157, and Lumbar-CPT® 72158) 		
>	Known (based on imaging) CNS hemangioblastoma	See: PEDONC-4.2: Intracranial Low Grade Gliomas (LGG)		
>	Known renal cell carcinoma	See: <u>PEDONC-7.4: Pediatric Renal</u> <u>Cell Carcinoma (RCC)</u>		
>	Known pheochromocytoma or other neuroendocrine tumor	See: ONC-15: Neuroendocrine Cancers And Adrenal Tumors in the Oncology Imaging Guidelines		

- Inherited in an autosomal dominant manner (50% risk to offspring), it is associated with CNS hemangioblastomas, retinal angiomas, endolymphatic sac tumors (ELST), gastrointestinal stromal tumor (GIST), renal cell carcinoma (RCC), pheochromocytomas, and other neuroendocrine tumors (NETs). Pediatric individuals are at risk of developing hemangioblastomas and pheochromocytomas that can remain clinically occult until symptoms become severe. Historically, substantial mortality was attributable to RCC, pancreatic NET, and CNS hemangioblastoma.
- Recommended cancer screening includes:
 - Annual ophthalmologic evaluation beginning at birth
 - Annual measurement of catecholamines beginning at age 2
 - Audiology assessment every 2 years beginning at age 5

PEDONC-2.11: Rhabdoid Tumor Predisposition Syndrome

The following imaging studies should be considered appropriate in individuals with Rhabdoid Tumor Predisposition Syndrome:

Indication	Imaging Study
 All individuals, from birth to 12 months of age 	 ALL of the following, monthly: US Head (CPT® 76506) US Abdomen (CPT® 76700) US Pelvis (CPT® 76856)
➤ All individuals, from age 1 to 5 years	 ALL of the following, every 3 months: MRI Brain (CPT® 70553) MRI Spine (CPT® 72156, CPT® 72157, & CPT® 72158) without and with contrast MRI Abdomen and Pelvis (CPT® 74183 & CPT® 72197) OR Ultrasound Abdomen and Pelvis (CPT® 76700 & CPT® 76856)
 Clinical symptoms present suggesting malignancy 	Targeted advanced imaging of the suspected disease site (CT with or without contrast or MRI with and without contrast)
> Inconclusive findings on ultrasound	 MRI with and without contrast of the inconclusive US site MRI should be used in place of ultrasound for remainder of planned screening

- Inherited in an autosomal dominant manner (50% risk to offspring), it is associated with malignant rhabdoid tumors of the kidney and extrarenal locations, and atypical teratoid/rhabdoid tumors (ATRT) of the CNS. It is caused by a germline mutation in *INI1* or *SMARCB1*, and is associated with a more variable prognosis than de novo rhabdoid tumors
- Note: Whole-body MRI resolution may not be sufficient to detect small rhabdoid tumors, so is not recommended in lieu of conventional MRI studies

PEDONC-2.12: Familial Retinoblastoma Syndrome

The following imaging studies should be considered appropriate in individuals with Familial Retinoblastoma Syndrome:

Indication	Imaging Study
Individuals with retinomas (premalignant retinal lesions)	> Annual MRI Orbits (CPT® 70543)
 Either of the following: Inconclusive EUA findings New symptoms 	 US Orbits (CPT® 76512, 76510, or 76511) or MRI Orbits (CPT® 70543) These studies should be used if at all possible in lieu of CT or nuclear imaging to avoid radiation exposure

- This syndrome is inherited in an autosomal dominant manner (50% risk to offspring). As the name suggests, it is associated with retinoblastoma, as well as osteosarcoma, pediatric melanoma, and a significantly increased risk for radiation-related malignancies.
- Regular physical and ophthalmologic evaluations under anesthesia (EUA) are the hallmark of surveillance strategies for these individuals, and asymptomatic screening imaging does not have a defined role at this time.

<u>PEDONC-2.13: Hereditary Paraganglioma-Pheochromocytoma (HPP)</u> Syndromes

The following imaging studies should be considered appropriate in individuals with HPP Syndromes:

Indication	Imaging Study
 All individuals with SDHx mutations, beginning at age 6 	 Every 2 years, ONE of the following sets of imaging: Whole-body MRI (CPT® 76498) CPT® 76498 is the only approvable code for whole-body MRI at this time OR MRI Neck (CPT® 70543), Chest (CPT® 71552), Abdomen (CPT® 74183), Pelvis (CPT® 72197) without and with contrast OR If MRI cannot be performed: CT Neck (CPT® 70491), Chest (CPT® 71260), and Abdomen and Pelvis (CPT® 74177) with contrast
Known pheochromocytoma or other neuroendocrine tumors	See: ONC-15: Neuroendocrine Cancers and Adrenal Tumors in the Oncology Imaging Guidelines

- Caused by mutations in SDHx genes, this syndrome is inherited in an autosomal dominant manner (50% risk to offspring), and is associated with pheochromocytomas and paragangliomas
- Individuals with multiple endocrine neoplasias should not use this guideline and should be imaged according to <u>PEDONC-2.8: Multiple Endocrine Neoplasias</u> (<u>MEN</u>).
- MRI is preferred to CT to minimize radiation exposure given these individuals' lifelong need for screening
- > All individuals with HPP receive annual measurement of catecholamines

PEDONC-2.14: Costello Syndrome

The following imaging studies should be considered appropriate in individuals with Costello Syndrome:

Indication	Imaging Study
 Following confirmation of gene mutation 	 ANY or ALL of the following: Echocardiogram CPT® 93306 or CPT® 93308 with CPT® 93321 and CPT® 93325 MRI Brain (CPT® 70553) without and with contrast MRI Cervical (CPT® 72156) and Thoracic Spine (CPT® 72157) without and with contrast
 All individuals, from birth to 10th birthday 	 Every 3 months: US Abdomen (CPT® 76700) and Pelvis (CPT® 76856)
> Known cardiac disease	 See: PEDCD-8.2: Initial Transthoracic Echocardiography (TTE) Indications and PEDCD-8.3: Repeat Transthoracic Echocardiography Indications in the Pediatric Cardiology Guidelines
> Known rhabdomyosarcoma	See: PEDONC-8.2: Rhabdomyosarcoma (RMS)
Known neuroblastoma	> See: PEDONC-6: Neuroblastoma

Background and Supporting Information

➤ Caused by mutations in HRAS genes, this syndrome is inherited in an autosomal dominant manner (50% risk to offspring), and is associated with rhabdomyosarcoma and neuroblastoma in early childhood, and transitional cell cancer of the bladder in older children and adults.

<u>PEDONC-2.15: Constitutional Mismatch Repair Deficiency (CMMRD or Turcot Syndrome)</u>

The following imaging studies should be considered appropriate in individuals with CMMRD/Turcot Syndrome:

Indication	Imaging Study
 All individuals, after CMMRD diagnosis is confirmed by genetic mutation 	 MRI Brain without and with contrast (CPT[®] 70553) every 6 months
All individuals, beginning at age 4 years	Annual esophagogastroduodenoscopy and colonoscopy
 All individuals, beginning at age 6 years 	 Annual whole-body MRI (CPT® 76498) CPT® 76498 is the only approvable code for whole-body MRI at this time

Background and Supporting Information

A highly penetrant and aggressive cancer predisposing syndrome resulting from autosomal recessive inheritance of biallelic mutations in mismatch repair genes, CMMRD syndrome leads to substantial risk for several commonly fatal childhood malignancies - high-grade CNS tumors (glioma, PNET, medulloblastoma) and hematologic malignancies (non-Hodgkin lymphoma, acute lymphoblastic leukemia). CMMRD individuals are also at increased risk for gastrointestinal tumors.

<u>PEDONC-2.16: Hereditary Leiomyomatosis and Renal Cell Cancer</u> (HLRCC)

The following imaging studies should be considered appropriate in individuals with HLRCC:

Indication	Imaging Study
 Beginning at age 8 years, individuals with at least ONE of the following: Documented fumarate hydratase (FH) gene mutation/variant consistent with HLRCC Histologically confirmed multiple cutaneous piloleiomyomas At least TWO of the following manifestations: Surgical treatment for symptomatic uterine leiomyomas before age 40 Type 2 papillary renal cell carcinoma or collecting duct renal carcinoma before age 40 A first-degree family member with either of the two above criteria 	➤ MRI Abdomen with and without contrast (CPT® 74183), annually

- Hereditary leiomyomatosis and renal cell cancer (HLRCC) is a disorder in which affected individuals tend to develop benign tumors containing smooth muscle tissue (leiomyomas) in the skin and, in females, the uterus. Approximately 20 percent of people with HLRCC develop renal cell cancer. People with HLRCC are commonly diagnosed with kidney cancer in their forties but cases have been reported in individuals as young as 11.
- In 2019, Forde et al published the first large, prospective study of screening for HLRCC and showed that most symptomatic individuals present with stage 3 or 4 RCC with a high risk of death, and one life is saved for every 5 individuals on an MRI screening protocol.

PEDONC-2.17: Other Renal Cell Cancer Predisposition Syndromes

Birt-Hogg-Dube Syndrome (BHDS)

The following imaging studies should be considered appropriate in individuals with BHDS:

Indication	Imaging Study
All individuals, beginning at age 20	MRI Abdomen with and without
years	contrast (CPT® 74183) every 3 years

Background and Supporting Information

- Birt-Hogg-Dube Syndrome (BHDS) in an autosomal dominant disorder with a heterozygous pathogenic variant in FLCN gene.
- These individuals have, or may have:
 - Cutaneous manifestations (fibrofolliculomas, acrochordons, angiofibromas, oral papules, cutaneous collagenomas, and epidermal cysts)
 - Pulmonary cysts/history of pneumothorax
 - A seven-fold increase in renal tumors
 - The most common renal tumors are oncocytoma, chromophobe, and a hybrid of these two.
 - Renal tumors may be multifocal and bilateral.
 - Median age of renal tumor diagnosis is 48 years.
- Recommended cancer screening includes:
 - Screening colonoscopy starting at age 40
 - Earlier colonoscopy may be considered for those with a family history of colorectal cancer earlier than age 40.

BAP1 Tumor Predisposition Syndrome

The following imaging studies should be considered appropriate in individuals with BAP1:

Indication Imaging Study	
All individuals, beginning at age 30	MRI Abdomen with and without
years	contrast (CPT® 74183) every 2 years

Background and Supporting Information

➤ BAP1 tumor predisposition syndrome (TPDS) is an autosomal dominant condition with a predisposition to melanoma (ocular and cutaneous), mesothelioma, clear cell renal cancer, and chromophobe renal cancer.

Hereditary Papillary Renal Carcinoma (HPRC)

The following imaging studies should be considered appropriate in individuals with HPRC:

Indication	Imaging Study
All individuals, beginning at age 30	MRI Abdomen with and without
years	contrast (CPT® 74183) every 2 years

Background and Supporting Information

Hereditary papillary renal carcinoma (HPRC) is an autosomal dominant condition involving the MET gene and predisposes individuals to multifocal, bilateral renal tumors.

Other Renal Predisposition Syndromes

The following imaging studies should be considered appropriate in individuals with other renal predisposition syndromes:

Indication	Imaging Study
 Individuals with any of the following genetic variants or syndromes: REST, TRIM28, FBXW7, NYNRIN, KDM3B, XPO5, CHECK2, PALB2, CTNNB1, DROSHA, WT1 and 2, WTX, DGCR8, SIC1 and 2, BCORL1, MLLT1, MYCN Frasier Syndrome Trisomy 18 Perlman Syndrome Bohring-Opitz Syndrome (ASXL1) MULIBREY and Nanism Syndrome Congenital anomalies associated with Wilms Tumor Horseshoe kidney Renal ectopia, hypoplasia or renal/ureteral duplication Congenital mesoblastic nephroma 	 Every 3 months, from birth to the 8th birthday: Abdominal US (CPT® 76700)

Background and Supporting Information

The list of syndromes and congenital anomalies associated with Wilms Tumor specifically is ever growing. Genetic variants and syndromes, not otherwise listed in PEDONC-2 for more specific imaging, may have imaging as shown above.

PEDONC-2.18: Infantile Myofibromatosis

The following imaging studies should be considered appropriate in individuals with Infantile Myofibromatosis:

	Indication		Imaging Study
>	Assess for the presence of multifocal disease in children under two years of age	>	WBMRI (CPT® 76498) once within 6 months of diagnosis
* *	Pre-operative planning or Signs or symptoms suggesting progression that may require treatment with surgery or chemotherapy	*	Imaging of cutaneous/muscular sites with MRI with and without contrast of symptomatic sites or sites requiring treatment.
>	Unresected, known visceral sites of disease	*	MRI with and without contrast of unresected visceral involved sites, every 6 months until the age of two years
>	Post-operative evaluation and both of the following: ◆ Adequacy of resection is unclear and ◆ Re-excision is being considered	*	One-time MRI with and without contrast
>	Surveillance for emergence of visceral disease	^	Every 6 months, until the age of two years: CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250) CT Abdomen and Pelvis (CPT® 74177) CT should not duplicate simultaneous
			MRI imaging of involved sites
>	Patients requiring chemotherapy	>	See: PEDONC-8.3

- Infantile myofibromatosis is a benign condition characterized by soft tissue tumors, 90% of which present in the first 2 years of life. 75% of cases present as solitary lesions affecting the skin and/or muscles of the head, neck and trunk. Other patterns of inheritance include congenital multicentric disease limited to skin and muscle, congenital multicentric with a single visceral site, and congenital with multiple visceral site involvement.
- The condition is most commonly sporadic, though familial cases associated with PDGFRB and NOTCH3 have been described
- The majority of cases with skin or muscle only involvement regress spontaneously.
- Visceral cases are lethal in the absence of therapy in 75% of cases due to organ compression, particularly with cardiopulmonary involvement.
- If vital structures are involved or significant symptoms occur, treatment is generally radical resection. Chemotherapy is sometimes utilized for progressive or multifocal life threatening lesions.
- Infants may present with a single lesion and develop further lesions in the first two years of life. This scenario, along with the inability of infants to readily express symptoms, impacts the imaging studies that may be approved.
- Routine surveillance of cutaneous/muscular sites is not supported as spontaneous regression is common.
- Surveillance beyond the age of two years is not supported.

PEDONC-3: Pediatric Leukemias	
PEDONC-3.1: Pediatric Leukemia General Considerations	53
PEDONC-3.2: Acute Lymphoblastic Leukemia (ALL)	
PEDONC-3.3: Acute Myeloid Leukemia (AML)	56

PEDONC-3.1: Pediatric Leukemia General Considerations

- MRI Brain without and with contrast (CPT® 70553) in individuals exhibiting CNS symptoms
 - Imaging due to CSF tumor burden has not been shown to improve the detection of CNS involvement compared with CSF alone
- See: <u>ONC-29: Hematopoietic Stem Cell Transplantation</u> for imaging guidelines related to transplant

Background and Supporting Information

- The overwhelming majority of leukemias occurring in children are acute. Chronic myelogenous leukemia (CML) is rare in children, and the occurrence of chronic lymphocytic leukemia (CLL) appears to have only been reported once in pediatric individuals to date
- Routine advanced imaging is not indicated in the evaluation and management of chronic myeloid leukemia in the absence of specific localizing clinical symptoms or clearance for hematopoietic stem cell transplantation

PEDONC-3.2: Acute Lymphoblastic Leukemia (ALL)

- Individuals with B-precursor or T-cell lymphoblastic lymphoma without bone marrow involvement are treated similarly to leukemia individuals of the same cell type and should be imaged according to this guideline section
- This section does not apply to individuals with mature B-cell histology (primarily Burkitt's in children). See: <u>PEDONC-5.3: Pediatric Aggressive Mature B-Cell Non-Hodgkin Lymphomas (NHL)</u> for guidelines for these individuals
- Scrotal Ultrasound CPT® 76870 and/or doppler ultrasound of the scrotum CPT® 93975 or 93976 may be approved for suspected testicular involvement.
- Chest x-ray should be performed to evaluate for mediastinal mass in suspected cases or upon initial diagnosis
 - CT Chest with contrast (CPT[®] 71260) immediately to evaluate for airway compression and anesthesia safety prior to attempting histologic diagnosis if mediastinal widening is seen on chest x-ray
 - Individuals with known or strongly suspected T-cell histology or other suspected lymphoblastic lymphoma involvement EITHER of the following for initial staging purposes:
 - CT Neck (CPT® 70491), CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast OR
 - PET/CT (CPT® 78816)
 - Indications and coding for rare circumstances where PET/MRI may be approved are found in <u>PEDONC-1.4: PET Imaging in Pediatric Oncology</u>

- MRI Brain without and with contrast (CPT® 70553) for individuals exhibiting CNS symptoms
 - Imaging due to CSF tumor burden has not been shown to improve the detection of CNS involvement compared with CSF alone.

<u>Additional imaging in lymphoblastic lymphoma/lymphomatous</u> extramedullary disease:

- CT to assess response to therapy only for individuals with known bulky nodal disease (usually with T-cell histology) at the end of induction (4 to 6 weeks). Individuals with residual masses can be evaluated with every new therapy phase (consolidation, interim maintenance, etc., generally every 8 to 12 weeks) until disease resolution is seen
- PET/CT (CPT® 78815) when residual mass ≥8 mm in diameter is present on recent CT imaging and immediate radiation or chemotherapy plan will be based on results.
 - Residual mass of any size with no PET-avidity is considered a complete response at the extranodal/lymphomatous site.
- Chest x-ray or Abdominal ultrasound (CPT® 76700) only, as indicated by site(s) of bulky disease present at diagnosis, for further surveillance, once CT imaging shows no evidence of disease.
- CT of all involved bulky nodal areas for individuals with persistent residual masses performed as part of an end of therapy evaluation

Immunosuppression during ALL therapy:

- CT or MRI requests for infectious disease concerns for individuals with ALL with:
 - Absolute neutrophil count (ANC) <500 or
 - Inconclusive findings on chest x-ray or ultrasound at any ANC during active treatment
- MRA/MRV Head (CPT® 70544, CPT® 70545, or CPT® 70546)
 - To rule out bleeding associated with sinus venous thrombosis in individuals treated with asparaginase

Imaging during therapy for relapsed ALL:

- Frequent CT or MRI to evaluate known or suspected new sites of invasive fungal or other aggressive infections
- Surveillance imaging of asymptomatic individuals to detect invasive fungal infection only when acute clinical decisions will be made based on the imaging

Imaging of known or suspected osteonecrosis in ALL:

- MRI without contrast or without and with contrast of the affected joint(s) with symptoms suggesting osteonecrosis
 - CT without contrast when MRI is contraindicated or unavailable or for diagnosis of suspected subchondral fracture

- MRI Bilateral Hips (CPT® 73721 or CPT® 73723 with modifier -50) once at 6 to 9 months after diagnosis for individuals age ≥11 years
- Repeat MRI without contrast of the affected joint(s) every 2 cycles of maintenance (every 6 months) if reintroduction of corticosteroids is being considered in individuals whose symptoms have resolved and are still receiving active treatment
- MRI without contrast of the affected joint(s) for preoperative planning for individuals undergoing core decompression
- See: <u>PEDONC-19.4: Osteonecrosis in Long Term Cancer Survivors</u> for information on osteonecrosis in ALL individuals who have completed therapy

- The majority of individuals with ALL have B-precursor ALL and routine advanced imaging is not necessary.
- Individuals with ALL are severely immunocompromised during the first 4 to 6 weeks of treatment (induction) and any conventional imaging request to evaluate for infectious complications during this time frame should be approved immediately
- Individuals with ALL who relapse are treated with very intensive chemotherapy regimens and most spend the majority of their chemotherapy treatment phase in the hospital
- Individuals may have therapy-induced hypogammaglobulinemia which requires supplemental intravenous immune globulin (IVIG) during maintenance therapy. Those receiving supplemental IVIG should be treated similarly to those with ANC <500 with regards to imaging for infectious disease</p>
- Osteonecrosis (ON) in individuals with ALL is a relatively common complication of ALL and its treatment, primary corticosteroids. Approximately 3% of younger children and 12 to 15% of adolescents are affected by ON at some point during therapy. The peak incidence occurs approximately one year from the time of diagnosis
- Screening MRI of asymptomatic individuals age ≤10 years to detect osteonecrosis has not been shown to impact outcomes, and it is not standard to alter treatment based on imaging findings alone without symptoms
- If osteonecrosis is detected on initial MRI, corticosteroids are often withheld during maintenance chemotherapy (but continued in earlier phases of therapy)

PEDONC-3.3: Acute Myeloid Leukemia (AML)

- Frequent CT or MRI imaging to evaluate known sites of invasive fungal infection due to the high risk of invasive infections
- Surveillance imaging of asymptomatic individuals to detect invasive fungal infection only when acute clinical decisions will be made based on the imaging

- The majority of AML individuals do not have any bulky disease and routine advanced imaging is not necessary
- Advanced imaging may be indicated for rare individuals with bulky tumor masses (commonly referred to as chloromas, leukemic sarcomas, or myeloid sarcomas) noted on physical examination or other imaging such as plain film or ultrasound
- AML individuals are treated with very intensive chemotherapy regimens and spend the majority of their chemotherapy treatment phase in the hospital

PEDONC-4: Pediatric CNS Tumors	
PEDONC-4.1: Pediatric CNS Tumors General Considerations	59
PEDONC-4.2: CNS Low Grade Gliomas (LGG)	62
PEDONC-4.3: CNS High Grade Gliomas (HGG)	65
PEDONC-4.4: Medulloblastoma (MDB), Supratentorial Primitive	
Neuroectodermal Tumors (sPNET), and Pineoblastoma	68
PEDONC-4.5: Atypical Teratoid/Rhabdoid Tumors (ATRT)	71
PEDONC-4.6: Pineocytomas and Pineal Parenchymal Tumors	73
PEDONC-4.7: CNS Germinomas and Non-Germinomatous Germ	Cell
Tumors (NGGCT)	75
PEDONC-4.8: Ependymoma	77
PEDONC-4.9: Malignant Tumors of the Spinal Cord	80
PEDONC-4.10: Craniopharyngioma and Other	
Hypothalamic/Pituitary Region Tumors	81
PEDONC-4.11: Primary CNS Lymphoma	83
PEDONC-4.12: Meningiomas	83
PEDONC-4.13: Choroid Plexus Tumors	84

PEDONC-4.1: Pediatric CNS Tumors General Considerations

➤ Central nervous system tumors are the second most common form of childhood cancer, accounting for ~20% of all pediatric malignancies

Red Flag Symptoms Raising Suspicion for CNS Tumors Include:

Any headache complaint from a child age ≤5 years

Headaches awakening from sleep

Focal findings on neurologic exam

Clumsiness (common description of gait or coordination problems in young children)

Headaches associated with morning nausea/vomiting

New onset of seizure activity with focal features

Papilledema on physical exam

MRI Considerations

- MRI is the preferred imaging modality for all pediatric CNS tumors
 - ◆ MRI Brain without and with contrast (CPT® 70553) is the primary imaging study for pediatric brain tumors
 - MRI Brain without contrast (CPT® 70551) if requested for initial evaluation of suspected CNS tumor for children able to undergo MRI without sedation
 - Initial MRI should be performed without and with contrast in order to avoid a second anesthesia exposure in younger children requiring sedation for MRI
- MRI Spine with contrast only (Cervical-CPT® 72142, Thoracic-CPT® 72147, Lumbar-CPT® 72149) can be substituted where MRI Spine without and with contrast is indicated, if being performed immediately following a contrast-enhanced MRI Brain

CT Considerations

- CT for evaluation of ventriculomegaly or other operative considerations, or for children who cannot undergo MRI safely
 - CT for evaluation of headaches related to head trauma or evaluation of skull or facial bone abnormalities
- ➤ CT is not a recommended study for evaluation of pediatric headache when brain tumor is clinically suspected because of its limited diagnostic accuracy in this area. MRI should be used as first line imaging in these cases
- CT should not be used in place of MRI to avoid sedation in young children when red flag symptoms for CNS tumors are present

MRA/CTA and Perfusion Studies

- MRA or CTA only for preoperative planning or to clarify inconclusive findings on MRI or CT
- CT and MRI Perfusion
 - See: <u>HD-24.5: CT or MRI Perfusion</u> in the Head Imaging guidelines

MR Spectroscopy (MRS, CPT® 76390)

- MRS is only supported for use in brain tumors of specified histologies where diagnostic accuracy has been established in peer-reviewed literature.
 - See diagnosis-specific guidelines for MRS indications
- MRS is considered investigational/experimental for all other histologies and indications not listed in a diagnosis-specific guideline section
- MR Spectroscopy is not indicated for routine surveillance

PET Brain Imaging (CPT® 78608 and CPT® 78609)

- ➤ PET Brain Metabolic imaging (CPT® 78608) is **only** supported for use in brain tumors of specified histologies where diagnostic accuracy has been established in peer-reviewed literature
 - See diagnosis-specific guidelines for PET indications
- > PET Brain Metabolic is not indicated for routine surveillance
- PET Brain Metabolic imaging is considered investigational/experimental for all other histologies and indications not listed in a diagnosis-specific guideline section
- ➤ PET Brain Perfusion imaging (CPT® 78609) is not indicated in the evaluation or management of primary CNS tumors
- ➤ Fusion PET/CT studies (CPT® 78814, CPT® 78815, or CPT® 78816) are not indicated in the evaluation or management of primary CNS tumors

Timing and Frequency of Imaging

- Definitive imaging should be completed prior to considering biopsy given the high degree of morbidity associated with operating on the CNS
 - Occasionally biopsy is not necessary because the imaging findings provide a definitive diagnosis
 - Examples include diffuse intrinsic pontine gliomas and optic pathway gliomas in an individual with known neurofibromatosis
- Perioperative Imaging Frequency
 - Children may undergo very frequent imaging in the immediate perioperative period around resection or debulking of a CNS tumor due to the small anatomic spaces involved
 - Requests for imaging during this time period to specifically evaluate postoperative course or ventriculoperitoneal shunt functioning should, in general, be approved as requested

- MRI Brain without and with contrast (CPT® 70553) one time in the immediate preoperative period (even if another study has already been completed) to gain additional information which can be important in optimizing individual outcomes, such as:
 - Completion of additional specialized MRI sequences such as diffusion-tensor imaging
 - Perfusion imaging
 - Tractography
 - Other sequences not reported under a separate CPT[®] code but not part of a routine MRI Brain series
- Repeat MRI Brain that is being requested solely for loading into operative navigation software should not be requested as a diagnostic code, but can be approved under a treatment planning code (CPT® 76498).

PEDONC-4.2: CNS Low Grade Gliomas (LGG)

> MR Spectroscopy and PET Brain Metabolic are not indicated for routine surveillance

Indication	Imaging Study
Initial staging of all LGG	 MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
 EITHER of the following: Determining the need for biopsy when transformation to high grade glioma is suspected based on clinical symptoms or recent MRI findings Evaluation of a brain lesion of indeterminate nature when the PET findings will be used to determine whether biopsy/resection can be safely postponed 	> PET Brain Metabolic imaging (CPT® 78608)
 ANY of the following: Distinguish low grade from high grade gliomas Evaluate a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed Distinguish radiation-induced tumor necrosis from progressive disease within 18 months of completing radiotherapy 	➤ MR Spectroscopy (MRS, CPT® 76390)
Baseline imaging after resection, to assess degree of resection	 MRI Brain without and with contrast (CPT® 70553) MRI with and without contrast at level of resected spinal site
Treatment response at the completion of radiotherapy	 MRI Brain without and with contrast (CPT® 70553) MRI with and without contrast at level of irradiated spinal site
Treatment response on chemotherapy	MRI Brain without and with contrast (CPT® 70553) approved every 2 cycles during active treatment and at the end of planned chemotherapy

Indication	Imaging Study
Additional treatment response imaging during induction chemotherapy for individuals with measurable spinal cord disease on MRI	MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) every 2 cycles
Surveillance	 For individuals with intracranial primary: MRI Brain without and with contrast (CPT® 70553) every 3 months for 2 years, then every 6 months for 3 years, then annually thereafter MRI Spine is not indicated during surveillance in patients without prior history of spinal involvement except to evaluate symptoms suspicious for spinal cord recurrence For individuals with a prior history of spine primary tumor or metastatic spinal involvement: MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) every 3 months for 2 years, then every 6 months for 3 years, then annually thereafter
Surveillance imaging for individuals with optic pathway glioma and either a history of intra-orbital involvement or a history of NF1	 Every 3 months for 2 years, then every 6 months for 3 years, then annually thereafter: MRI Brain without and with contrast (CPT® 70553) and MRI Orbits without and with contrast (CPT® 70543)
Suspected intracranial or intraspinal recurrence	 All imaging supported in initial staging criteria may be repeated
Suspected spinal cord recurrence	MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Includes the following tumors:

- Pilocytic Astrocytoma
- Fibrillary (or Diffuse) Astrocytoma
- Optic Pathway Gliomas
- Pilomyxoid Astrocytoma
- Oligodendroglioma
- Oligoastrocytoma
- Oligodendrocytoma
- Subependymal Giant Cell Astrocytoma (SEGA)
- Ganglioglioma
- Gangliocytoma
- Dysembryoplastic Infantile Astrocytoma (DIA)
- Dysembryoplastic Infantile Ganglioglioma (DIG)
- Dysembryoplastic Neuroepithelial Tumor (DNT)
- Tectal Plate Gliomas
- Cervicomedullary Gliomas
- Pleomorphic Xanthoastrocytoma (PXA)
- Any other glial tumor with a WHO grade of I or II

General Considerations:

- > Account for 40 to 60% of pediatric CNS tumors.
- These tumors are defined as having a WHO histologic grade of I or II (out of IV), can occur anywhere in the CNS

Treatment Considerations:

- Children with neurofibromatosis and small optic pathway tumors may not undergo biopsy or resection and will proceed directly to treatment or surveillance
- Children on observation without specific treatment should be imaged according to surveillance guidelines for LGG
- Individuals who undergo complete resection should be imaged according to surveillance guidelines after post-resection imaging
- Individuals age >10 years with incompletely resected tumors usually receive adjuvant radiation therapy
- Individuals age ≤10 years with incompletely resected tumors are commonly treated with chemotherapy

PEDONC-4.3: CNS High Grade Gliomas (HGG)

Indication	Imaging Study
Initial staging of all HGG	 MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
 ANY of the following: Distinguishing radiation-induced tumor necrosis from progressive disease within 18 months of completing radiotherapy Evaluating inconclusive MRI findings when the PET findings will be used to determine need for biopsy or change in therapy, including a change from active therapy to surveillance Evaluation of a brain lesion of indeterminate nature when the PET findings will be used to determine whether biopsy/resection can be safely postponed 	➤ PET Brain Metabolic Imaging (CPT® 78608)
 ANY of the following: To distinguish low grade from high grade gliomas To evaluate a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed To distinguish radiation-induced tumor necrosis from progressive disease within 18 months of completing radiotherapy 	> MR Spectroscopy (MRS, CPT® 76390)
Baseline imaging following resection, to assess degree of resection	 MRI Brain without and with contrast (CPT® 70553) MRI with and without contrast at level of resected spinal site
Treatment response at the completion of radiotherapy	 MRI Brain without and with contrast (CPT® 70553) MRI with and without contrast at level of irradiated spinal site
Treatment response on chemotherapy	MRI Brain without and with contrast (CPT® 70553) every 2 cycles during active treatment and at the end of planned chemotherapy

Indication	Imaging Study
Additional treatment response imaging during induction chemotherapy for individuals with measurable spinal cord disease on MRI	 MRI Spine without and with contrast (Cervical-CPT[®] 72156, Thoracic-CPT[®] 72157, Lumbar-CPT[®] 72158) every 2 cycles
Surveillance	 For individuals with intracranial primary: MRI Brain without and with contrast (CPT® 70553) every 3 months for 3 years, then every 6 months thereafter MRI Spine is not indicated during surveillance in individuals without prior history of spinal involvement except to evaluate symptoms suspicious for spinal cord recurrence For individuals with a history of spine primary tumor or metastatic spinal involvement: MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) every 3 months for 3 years, then every 6 months thereafter
Suspected intracranial or intraspinal	All imaging supported for initial staging
recurrence	may be repeated
Suspected spinal cord recurrence	 MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Includes the following tumors:

- Anaplastic astrocytoma
- Glioblastoma multiforme
- Diffuse intrinsic pontine glioma (DIPG, or "Brainstem glioma")
- Gliomatosis cerebri
- Gliosarcoma
- Anaplastic oligodendroglioma
- Anaplastic ganglioglioma
- Anaplastic mixed glioma
- Anaplastic mixed ganglioneuronal tumors
- Any other glial tumor with a WHO grade of III or IV

General Considerations:

- Rare in children compared with the adult population, but represent 10 to 20% of pediatric CNS tumors
- Prognosis is very poor, and survival significantly beyond 3 years from diagnosis is rare, even with complete surgical resection at initial diagnosis
- These tumors are defined as having a WHO histologic grade of III or IV (out of IV) can occur anywhere in the CNS (though the majority occur in the brain)

Treatment Considerations:

- Individuals who undergo complete resection should be imaged according to surveillance guidelines after post-resection imaging
- Individuals with incompletely resected tumors are commonly treated with chemotherapy

PEDONC-4.4: Medulloblastoma (MDB), Supratentorial Primitive Neuroectodermal Tumors (sPNET), and Pineoblastoma

MR Spectroscopy and PET Brain Metabolic are not indicated for routine surveillance

Indication	Imaging Study
Initial staging for all individuals, preoperatively	 MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
 ANY of the following: To distinguish radiation-induced tumor necrosis from progressive disease within 18 months of completing radiotherapy To evaluate inconclusive MRI findings when the PET findings will be used to determine need for biopsy or change in therapy, including a change from active therapy to surveillance To evaluate a brain lesion of indeterminate nature when the PET findings will be used to determine whether biopsy/resection can be safely postponed 	➤ PET Brain Metabolic Imaging (CPT® 78608)
 ANY of the following: To evaluate a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed 	➤ MR Spectroscopy (CPT® 76390)
Postoperative (preferably within 48 hours of surgery) to quantify residual tumor volume	 MRI Brain without and with contrast (CPT[®] 70553)
Within 28 days post-op, if spinal imaging was not performed preoperatively	MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Indication	Imaging Study
Treatment response	 At the start of adjuvant chemotherapy and every 2 cycles until therapy is completed: MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic CPT® 72157, Lumbar-CPT® 72158)
Children age <3 years treated with multiple cycles of high dose chemotherapy with autologous stem cell rescue in lieu of radiotherapy	Disease evaluations (imaging per treatment response guidelines) may occur prior to each cycle (every 4 to 6 weeks) if needed for response determination.
End of treatment evaluation	 MRI Brain without and with contrast (CPT® 70553) MRI Spine with contrast (Cervical-CPT® 72142, Thoracic-CPT® 72147, Lumbar-CPT® 72149) or MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Surveillance	 Every 3 months for 3 years, then every 6 months for 2 years, then annually for 10 years: MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Includes the Following Tumors:

- Medulloblastoma and Pineoblastoma
- ➤ sPNET
 - Medulloepithelioma
 - Cerebral or cerebellar neuroblastoma
 - Cerebral or cerebellar ganglioneuroblastoma
 - Ependymoblastoma

Risk Assessment is Important in Determining Optimal Treatment High Risk Features Include the Following:

- Spinal metastasis (including cytology positive only)
- Multifocal intracranial tumors
- Anaplastic histology
- > All sPNET and pineoblastomas
- > 1.5 cm² residual tumor area on postoperative MRI and age <3 years

Individuals without any high risk features are considered "Average Risk"

General Considerations:

- Account for 15 to 25% of pediatric CNS tumors
- Prognosis is generally favorable
- Leptomeningeal spread is common and can occur after initial diagnosis

Treatment Considerations:

- Individuals generally proceed to chemoradiotherapy within 31 days of surgical resection
 - All individuals receive adjuvant chemotherapy lasting 6 to 12 months that begins
 6 weeks after completion of chemoradiotherapy

PEDONC-4.5: Atypical Teratoid/Rhabdoid Tumors (ATRT)

- > PET Brain Metabolic does not have a defined role in the evaluation of ATRT at this time
- > MR Spectroscopy is not indicated for routine surveillance

Indication	Imaging Study
Initial staging for all individuals, preoperatively	 MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) Renal US (CPT® 76770) If renal US is abnormal, refer to: PEDONC-7.6: Malignant Rhabdoid Tumor of the Kidney (MRT) and Other Extracranial Sites
Evaluation of a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed	➤ MR Spectroscopy (CPT® 76390)
Postoperative (preferably within 48 hours of surgery) to quantify residual tumor volume	 MRI Brain without and with contrast (CPT® 70553)
Within 28 days post-op, if spinal imaging was not performed preoperatively	 MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Treatment response to induction chemotherapy	 After every 2 cycles: MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Individuals treated with consolidation chemotherapy and autologous stem cell rescue	Disease evaluation is indicated following the end of the planned stem cell rescues but may occur prior to each cycle (every 4 to 6 weeks) if needed for response determination
End of treatment evaluation	 MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Surveillance	 Every 3 months for 2 years, then every 6 months for 3 years, then annually for 10 years: MRI Brain without and with contrast (CPT® 70553)

Indication	Imaging Study
	 MRI Spine without and with contrast (Cervical-CPT[®] 72156, Thoracic-CPT[®] 72157, Lumbar-CPT[®] 72158)

General Considerations:

- Highly aggressive tumor occurring primarily in very young children that has a clinical presentation very similar to medulloblastoma with a much higher rate of leptomeningeal spread.
- Metastases can occur outside the CNS, and associated tumors can also arise in the kidneys (Malignant Rhabdoid Tumor of the Kidney, MRT).
 - Rhabdoid malignancies occurring outside the CNS should be imaged according to PEDONC-7.6: Malignant Rhabdoid Tumor of the Kidney (MRT) and Other Extracranial Sites.
- Overall prognosis is poor, with <20% of individuals surviving beyond 2 years from diagnosis.
- Individuals generally proceed to induction chemotherapy shortly following surgical resection or biopsy.
- Following completion of chemotherapy, some individuals will proceed to radiotherapy.
 - MRI performed at the end of consolidation therapy should serve as the diagnostic MRI prior to radiotherapy.

PEDONC-4.6: Pineocytomas and Pineal Parenchymal Tumors

Indication	Imaging Study
Initial staging for all individuals	 MRI Brain without and with contrast (CPT® 70553)
 Additional initial staging imaging for individuals with: Multicentric tumors Atypical histology including pineoblastoma-like elements (grade 2 or 3 pineal parenchymal tumors which have not been considered a pineoblastoma or PNET) Clinical signs or symptoms suggesting spinal cord involvement 	MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic- CPT® 72157, Lumbar-CPT® 72158)
Baseline imaging following resection	MRI Brain without and with contrast (CPT® 70553)
End of radiotherapy	 MRI Brain without and with contrast (CPT[®] 70553)
Additional imaging at end of radiotherapy for individuals with measurable spinal cord disease on MRI	 MRI Spine without and with contrast (Cervical-CPT[®] 72156, Thoracic- CPT[®] 72157, Lumbar-CPT[®] 72158)
Surveillance	MRI Brain without and with contrast (CPT® 70553) every 3 months for 1 year, then every 4 months for 1 year, then every 6 months for 1 year, then annually thereafter
Additional surveillance imaging for individuals with cord involvement at diagnosis	MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) after completion of therapy every 3 months for 1 year, then every 4 months for 1 year, then every 6 months for 1 year, then annually thereafter
Suspected spinal cord recurrence	 MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic- CPT® 72157, Lumbar-CPT® 72158)

General Considerations:

- Low grade malignancy that is similar in presentation to low grade glioma (LGG)
- PET Brain Metabolic imaging and MR Spectroscopy do not have a defined role in the evaluation of pineocytoma
- Surgical resection is curative for most individuals
 - Individuals with a complete resection should then be imaged according to surveillance guidelines
- Individuals with incompletely resected tumors may receive adjuvant radiation therapy
 - After end of radiotherapy imaging, these individuals should be imaged according to surveillance guidelines

PEDONC-4.7: CNS Germinomas and Non-Germinomatous Germ Cell Tumors (NGGCT)

PET Metabolic Brain imaging does not have a defined role in the evaluation of CNS GCT

Indication	Imaging Study
Initial staging for all individuals	 MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Evaluation of a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed	> MR Spectroscopy (CPT® 76390)
Treatment response to induction chemotherapy	 MRI Brain without and with contrast (CPT[®] 70553) every 2 cycles
Additional treatment response to induction chemotherapy for individuals with measurable spinal cord disease on MRI	 MRI Spine without and with contrast (Cervical-CPT[®] 72156, Thoracic-CPT[®] 72157, Lumbar-CPT[®] 72158) every 2 cycles
End of induction chemotherapy for individuals with localized intracranial tumors	 MRI Spine without and with contrast (Cervical-CPT[®] 72156, Thoracic-CPT[®] 72157, Lumbar-CPT[®] 72158)
Prior to second-look surgery	 MRI of all known sites of measurable disease
Prior to radiotherapy	 MRI of all known sites of measurable disease
At the end of all planned therapy	 MRI Brain without and with contrast (CPT® 70553) MRI Spine (with or without and with contrast)
Surveillance	 Every 3 months for 1 year, then every 4 months for 1 year, then every 6 months for 1 year, then annually until 5 years after completion of therapy: MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Individuals in long term follow up after CNS tumor treatment that included radiation therapy	See: <u>PEDONC-19.3: Second</u> <u>Malignant Neoplasms (SMN)</u>

Indication	Imaging Study
Suspected recurrence - new or worsening neurologic symptoms (including worsening of diabetes insipidus)	 MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Includes the Following Tumors:

- CNS Germinoma
- Non-Germinomatous Germ Cell Tumors (NGGCT)
 - Embryonal carcinoma
 - Yolk sac tumor
 - Choriocarcinoma
 - Teratoma
 - Mixed germ cell tumor

General Considerations:

- More common in older school age children and younger adolescents, but can occur throughout the pediatric age range
- Although leptomeningeal spread is common, prognosis is excellent due to high sensitivity to chemotherapy and radiotherapy
- Individuals generally proceed to chemotherapy shortly following surgical resection or biopsy and will usually receive 2 to 4 cycles
- Following completion of chemotherapy, individuals with residual disease will proceed to second-look surgery and/or radiotherapy

PEDONC-4.8: Ependymoma

- PET Brain Metabolic imaging does not have a defined role in the evaluation of ependymoma
- > MR Spectroscopy is not indicated for routine surveillance

Indication	Imaging Study
Initial staging for all individuals	 MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Evaluation of a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed	> MR Spectroscopy (CPT® 76390)
Baseline imaging following resection	MRI Brain without and with contrast (CPT® 70553) or MRI without and with contrast of involved spinal level(s)
Completion of radiotherapy	 MRI Brain without and with contrast (CPT[®] 70553) or MRI without and with contrast of involved spinal level(s)
Prior to radiotherapy	MRI of all known sites of measurable disease
Treatment response to induction chemotherapy	MRI Brain without and with contrast (CPT® 70553) or MRI without and with contrast of involved spinal level(s) every 2 cycles
End of induction chemotherapy and again at end of all therapy	 MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Prior to second-look surgery	 MRI of all known sites of measurable disease

Indication	Imaging Study
Surveillance, primary intracranial ependymoma and NO history of spinal cord involvement	 MRI Brain without and with contrast (CPT® 70553) every 3 months for 2 years, then every 4 months for 1 year, then every 6 months in years 4 and 5, then annually to 10 years post treatment MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) can be approved annually for 2 years

Indication	Imaging Study
Surveillance, primary intracranial ependymoma AND metastatic cord involvement at diagnosis	 MRI Brain without and with contrast (CPT® 70553) every 3 months for 2 years, then every 4 months for 1 year, then every 6 months in years 4 and 5, then annually to 10 years post treatment MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) every 3 months for 2 years, then every 4 months for 1 year, then every 6 months in years 4 and 5, then annually to 10 years post treatment
Surveillance, primary intra spinal ependymoma and NO history of intracranial involvement	 MRI without and with contrast of the involved spinal level(s) every 3 months for 2 years, then every 4 months for 1 year, then every 6 months in years 4 and 5, then annually to 10 years post treatment MRI Brain without and with contrast (CPT® 70553) every 3 months for 2 years, then every 4 months for 1 year, then every 6 months in years 4 and 5, then annually to 10 years post treatment
Surveillance, primary intra <u>spinal</u> ependymoma AND metastatic intracranial involvement at diagnosis	MRI Brain without and with contrast (CPT® 70553) and MRI of the involved spinal level(s) without and with contrast every 3 months for 2 years,

then every 4 months for 1 year, then
every 6 months in years 4 and 5, then
annually to 10 years post treatment

General Considerations:

- Occur primarily intracranially, roughly 2/3 in the posterior fossa
- Overall prognosis is very good, with supratentorial tumors faring better
- Primary spinal tumors can also occur, and are more common in adult individuals than pediatric individuals.
- Surgery is the primary treatment modality
 - Individuals with a complete resection should then be imaged according to surveillance guidelines
- Radiotherapy +/- chemotherapy is used for:
 - Incompletely resected tumors
 - Anaplastic histology
 - Infratentorial location
 - Individuals with incomplete resection or high risk histology that receive adjuvant radiation therapy should then be imaged according to surveillance guidelines after end of radiotherapy imaging.
- Individuals with gain of chromosome 1q have worse progression-free survival and overall survival outcomes
- RELA-fusion supratentorial ependymoma did not portend worse overall survival outcomes in recent Clinical Oncology Group studies, and is generally not considered an indication for more frequent surveillance imaging

PEDONC-4.9: Malignant Tumors of the Spinal Cord

- MRI Spine without and with contrast of all involved levels of the primary site(s) (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
 - Entire spine imaging may be indicated based on the histologic type
 - For rare histologies not specified in these guidelines, MRI of the total spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) should be approved for initial staging and every 2 cycles for treatment response.
- MRI Brain without and with contrast (CPT® 70553) at initial diagnosis, but may be not be necessary during treatment response and surveillance

- Treatment principles are the same as tumors of the brain, and should follow imaging guidelines according to the specific histologic type
- Multiple spinal cord tumors should raise suspicion for neurofibromatosis
- Common histologies of primary spinal cord tumor in children include:
 - Low Grade Glioma, see: <u>PEDONC-4.2: CNS Low Grade Gliomas (LGG)</u> for guidelines
 - High Grade Glioma, see: <u>PEDONC-4.3: CNS High-Grade Glioma (HGG)</u> for guidelines
 - Ependymoma, see: **PEDONC-4.8: Ependymoma** for guidelines
 - Any type of malignant spinal cord tumor can occur, but other histologies are rare
- Given the rarity of primary spinal cord tumors in children, MRI Brain requests should, in general, be approved for surveillance after recent evaluation by a physician with significant training and/or experience in pediatric spinal cord tumors (most commonly a pediatric neurosurgeon or pediatric oncologist) as the need for intracranial surveillance is highly individualized
- Asymptomatic surveillance imaging should generally end at the time point appropriate for the specific tumor type

PEDONC-4.10: Craniopharyngioma and Other Hypothalamic/Pituitary Region Tumors

➤ PET Brain Metabolic Imaging and MR Spectroscopy do not have a defined role in the evaluation of craniopharyngioma

the evaluation of cramopharyngioma	
Indication	Imaging Study
Initial staging for all individuals	 MRI Brain without and with contrast (CPT® 70553) Concurrent CT Head without contrast (CPT® 70450) can be approved in addition to MRI if craniopharyngioma is suspected
 Additional initial staging for individuals with: Multicentric tumors Clinical signs or symptoms suggesting spinal cord involvement 	 MRI Spine without and with contrast (Cervical-CPT[®] 72156, Thoracic-CPT[®] 72157, Lumbar-CPT[®] 72158)
Operative planning or image guidance	 MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) OR CTA Head (CPT® 70496)
Baseline imaging following resection	 MRI Brain without and with contrast (CPT[®] 70553)
Completion of radiotherapy	 MRI Brain without and with contrast (CPT[®] 70553)
Treatment response to chemotherapy	MRI Brain without and with contrast (CPT® 70553) approved every 2 cycles during active treatment and at the end of planned chemotherapy
Additional treatment response imaging during induction chemotherapy for individuals with measurable spinal cord disease on MRI	 MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) every 2 cycle
Surveillance	 MRI Brain without and with contrast (CPT® 70553) can be approved every 3 months for 1 year, then every 4 months for 1 year, then every 6 months for 1 year, then annually until 10 years after completion of therapy as late progressions can occur For additional imaging guidelines for individuals in long term follow up after CNS tumor treatment that included radiation therapy, see: PEDONC-19.3: Second Malignant Neoplasms (SMN)

Suspected spinal cord recurrence	MRI Spine without and with contrast (Cervical-CPT [®] 72156, Thoracic-CPT [®] 72157, Lumbar-CPT [®] 72158)
----------------------------------	---

General Considerations:

- Imaging guidelines and treatment approaches for pediatric pituitary tumors other than craniopharyngioma are consistent with those used for adults with pituitary tumors
 - For these tumors follow guidelines in <u>HD-19: Pituitary</u> in the Head Imaging Guidelines
- Craniopharyngiomas are less common, accounting for 6 to 8% of pediatric CNS tumors.
- Most commonly affects children in the preadolescent ages
- Several key imaging findings can be used to differentiate the tumors in this region including the presence of calcifications, cysts, and T1/T2 enhancement patterns in craniopharyngiomas
 - These are best evaluated using a COMBINATION of both MRI and CT modalities. Preoperative prediction is much more successful when BOTH modalities are obtained prior to biopsy.
- Other less common tumors in the optic chiasm, sella, and suprasella region may include Germ Cell Tumors (GCT, see: <u>PEDONC-4.7</u>) and Langerhans Cell Histiocytosis (LCH, see: <u>PEDONC-18</u>)

Treatment Considerations:

- Surgical resection is curative for many individuals
 - Those with a complete resection should then be imaged according to surveillance guidelines after post-resection imaging is completed
- ➤ Individuals with incomplete resection and receiving adjuvant radiation therapy can have a single MRI Brain (CPT® 70553) approved at completion of radiotherapy and should then be imaged according to surveillance guidelines

PEDONC-4.11: Primary CNS Lymphoma

- Primary CNS lymphoma imaging indications in pediatric individuals are identical to those in the general imaging guidelines. See: <u>ONC-2.7: CNS Lymphoma (also known as Microglioma)</u> in the Oncology Imaging Guidelines
- CNS Lymphomas also involving bone marrow and/or lymph nodes should be imaged according to: <u>PEDONC-5.3</u>: <u>Pediatric Aggressive Mature B-Cell Non-Hodgkin Lymphomas (NHL)</u>

Background and Supporting Information

- Primary CNS Lymphoma is a solitary or multifocal mass occurring in the brain without evidence of systemic (bone marrow or lymph node) involvement.
- Usually associated with immunodeficiency, this is a very rare entity in pediatrics accounting for <0.1% of pediatric malignancies, so age-specific guidelines have not been established

PEDONC-4.12: Meningiomas

- Meningioma imaging indications in pediatric individuals are identical to those in the general imaging guidelines
 - See: <u>ONC-2.8: Meningiomas (Intracranial and Intraspinal)</u> in the Oncology Imaging Guidelines

- Account for 1 to 3% of pediatric CNS tumors.
- Usually associated with neurofibromatosis type 2 (NF-2) or prior therapeutic radiation exposure to the brain.
 - Lifetime risk may be as high as 20% for young children receiving whole brain radiotherapy, most commonly occurring 15 to 20 years after radiation exposure

PEDONC-4.13: Choroid Plexus Tumors

PET Metabolic Brain imaging does not have a defined role in the evaluation of choroid plexus tumors

Choroid Plexus Papilloma:

Indication	Imaging Study
Suspected/Diagnosis	 MRI Brain without and with contrast (CPT® 70553)
Evaluation of a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed	➤ MR Spectroscopy (CPT® 76390)
Suspected return of hydrocephalus, or return of hydrocephalus seen on CT imaging	 MRI Brain without and with contrast (CPT[®] 70553)

Choroid Plexus Adenoma or Atypical Choroid Plexus Papilloma:

Indication	Imaging Study
Suspected/Diagnosis	 MRI Brain without and with contrast (CPT® 70553)
	 MRI Spine without and with contrast (Cervical-CPT[®] 72156, Thoracic- CPT[®] 72157, Lumbar-CPT[®] 72158)
Evaluation of a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed	> MR Spectroscopy (CPT® 76390)
Suspected return of hydrocephalus, or return of hydrocephalus seen on CT imaging	 MRI Brain without and with contrast (CPT® 70553)

Pediatric Oncology Imaging Guidelines

Choroid Plexus Carcinoma:

Indication	Imaging Study
Initial staging of all individuals	 MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Evaluation of a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed	> MR Spectroscopy (CPT® 76390)
Baseline imaging following resection	 MRI Brain without and with contrast (CPT® 70553)
Prior to radiotherapy	MRI Brain without and with contrast (CPT® 70553) and MRI with and without contrast of all known sites with measurable disease prior to radiotherapy.
Completion of radiotherapy	 MRI Brain without and with contrast (CPT® 70553)
Treatment response to chemotherapy	 MRI Brain without and with contrast (CPT® 70553) every 2 cycles during active treatment
Additional treatment response to chemotherapy for individuals with measurable spinal cord disease on MRI	 MRI Spine without and with contrast (Cervical-CPT[®] 72156, Thoracic-CPT[®] 72157, Lumbar-CPT[®] 72158) every 2 cycles during active treatment
Prior to second-look surgery	 MRI of all known sites of measurable disease
End of all planned therapy	 MRI Brain without and with contrast (CPT® 70553) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Indication	Imaging Study
Surveillance, no history of spinal cord involvement	 MRI Brain without and with contrast (CPT® 70553) every 4 months for 3 years, then every 6 months for 2 years after completion of therapy For additional imaging guidelines for individuals in long term follow up after CNS tumor treatment that included radiation therapy, See: PEDONC-19.3: Second Malignant Neoplasms (SMN) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) at 12 and 24 months after completion of therapy
Surveillance, individuals with cord involvement at diagnosis	 MRI Brain without and with contrast (CPT® 70553) every 4 months for 3 years, then every 6 months for 2 years after completion of therapy For additional imaging guidelines for individuals in long term follow up after CNS tumor treatment that included radiation therapy, see: PEDONC-19.3: Second Malignant Neoplasms (SMN) MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) every 4 months for 3 years, then every 6 months for 2 years after completion of therapy

- As a group these account for 1 to 4% of pediatric CNS tumors, and 70% of choroid plexus tumors present within the first 2 years of life
- Includes the following tumors:
 - Choroid plexus papilloma
 - Choroid plexus adenoma, or atypical choroid plexus papilloma
 - Choroid plexus carcinoma
- Choroid Plexus Papilloma
 - Choroid plexus papillomas outnumber other choroid plexus tumors by 4 to 5 times.
 - These ventricular tumors commonly present with hydrocephalus caused by increased CSF production, resulting in signs of increased intracranial pressure.
 - Appearance on MRI is typical, and they are usually treated by excision.
 - Regrowth is rare
- Choroid Plexus Adenoma or Atypical Choroid Plexus Papilloma
 - These are extremely rare tumors with features midway in the malignant spectrum between papillomas and carcinomas
 - They are more prone to local invasion, but rarely to metastasis
 - Presenting symptoms are similar to papillomas
 - Appearance on MRI is typical, and they are usually treated by excision
 - Spinal imaging may be approved if requested at initial diagnosis
 - Regrowth is rare
- Choroid Plexus Carcinoma
 - This is a very aggressive malignancy, with high rates of metastasis to other parts
 of the CNS
 - Overall incidence of metastases in choroid plexus carcinoma is 12–50%, which is associated with a worse outcome
 - Prognosis is significantly less favorable than for papillomas with overall survival rates of 35 to 40%
 - TP53 mutations and alternative lengthening telomeres (ALT) are common in individuals with choroid plexus carcinoma
 - Surgical gross total resection is curative for many individuals
 - Individuals with confirmed gross total resection should then be imaged according to surveillance guidelines
 - Individuals with incomplete resection who receive adjuvant radiation therapy should be imaged according to surveillance guidelines after end of radiotherapy imaging
 - MR Spectroscopy is not indicated for routine surveillance

PEDONC-5: Pediatric Lymphomas	
PEDONC-5.1: Pediatric Lymphoma - General Considerations	91
PEDONC-5.2: Pediatric Hodgkin Lymphoma (HL)	92
PEDONC-5.3: Pediatric Aggressive Mature B-Cell Non-Hodgkin	
Lymphomas (NHL)	95
PEDONC-5.4: Anaplastic Large Cell Lymphoma (ALCL)	98

PEDONC-5.1: Pediatric Lymphoma - General Considerations

- Lymphoma mostly commonly involves the lymph nodes (LNs). However, lymphoma can also arise from primary lymphoid tissues (bone marrow or thymus) or various secondary lymphoid tissues (spleen, mucosa-associated lymphoid tissue) or non-lymphoid organs (skin, bone, brain, lungs, liver, salivary glands, etc).
- Pediatric lymphomas are generally Hodgkin Lymphomas, Aggressive B-Cell Non-Hodgkin Lymphomas, Lymphoblastic Lymphomas, or Anaplastic Large Cell Lymphomas
- Individuals with Lymphoblastic Lymphoma (even those with bulky nodal disease) are treated using the leukemia treatment plan appropriate to the cell type (B or T cell)
 - These individuals should be imaged using guidelines in <u>PEDONC-3.2: Acute</u> <u>Lymphoblastic Leukemia (ALL)</u>
- Other histologies are rare in pediatric individuals, and should be imaged according to the following guidelines:
 - Follicular lymphoma: <u>ONC-27.3: Follicular Lymphoma</u> in the Oncology Imaging Guidelines
 - Marginal zone or MALT lymphomas: <u>ONC-27.4: Marginal Zone Lymphoma</u> in the Oncology Imaging Guidelines
 - Mantle cell lymphomas: <u>ONC-27.5: Mantle Cell Lymphoma</u> in the Oncology Imaging Guidelines
 - Cutaneous lymphomas: <u>ONC-27.8: Cutaneous Lymphoma and T Cell</u> <u>Lymphomas</u> in the Oncology Imaging Guidelines
 - Exception: Cutaneous B-Lymphoblastic Lymphoma should be imaged using guidelines in PEDONC-3.2: Acute Lymphoblastic Leukemia (ALL)
 - Castleman's Disease: <u>ONC-31.11: Castleman's Disease (Unicentric and Multicentric)</u> in the Oncology Imaging Guidelines
- All CT imaging recommended in this section refers to CT with contrast only
 - Noncontrast CT imaging has not been shown to be beneficial in the management of pediatric lymphomas
 - Given the limited utility of noncontrast CT imaging in pediatric lymphomas, MRI without or without and with contrast is recommended in place of CT for individuals who cannot tolerate CT contrast due to allergy or impaired renal function
- MRI without and with contrast of symptomatic or previously involved bony areas can be approved in known lymphoma individuals without prior plain x-ray or bone scan evaluation
 - Bone scan is inferior to MRI for evaluation of known or suspected bone metastases in lymphoma
- MRI Brain without and with contrast (CPT® 70553) is the preferred study for evaluation of suspected brain metastases in pediatric lymphoma
 - CT Head with (CPT® 70460) or without and with contrast (CPT® 70470) can be approved when MRI is contraindicated

PEDONC-5.2: Pediatric Hodgkin Lymphoma (HL)

Indication	Imaging Study	
	ANY or ALL of the following may be approved:	
	 CT Neck with contrast (CPT[®] 70491) 	
	 CT Chest with contrast (CPT® 71260) 	
	 CT Abdomen and Pelvis with contrast (CPT[®] 74177) 	
Initial staging	 CT with contrast or MRI without and with contrast of any other symptomatic body area 	
	> PET/CT (CPT® 78815 or CPT® 78816)	
	 Can be performed prior to biopsy if necessary for individual scheduling 	
	CT or MRI of other body areas may be indicated for rare individuals based on physical findings or PET/CT results	
	 ALL of the following, as often as every 2 cycles of chemotherapy: CT of previously involved visceral areas In individuals on treatment for recurrent or refractory Hodgkin Lymphoma, the following are indicated: CT Neck with contrast (CPT® 70491) CT Chest with contrast (CPT® 71260) CT Abdomen and Pelvis with contrast (CPT® 74177) MRI Brain with and without contrast (CPT® 70553) for known CNS involvement 	
Restaging	 After cycles 2 and 4 of chemotherapy* and at end of therapy: PET/CT (CPT® 78815 or CPT® 78816) *This restaging PET/CT may instead be performed after cycles 1 and 3 for individuals with low risk stage IA or IIA mixed cellularity Hodgkin lymphoma) 	
	 In addition to the above studies: A single follow-up PET/CT (CPT® 78815 or CPT® 78816) is indicated >12 weeks after radiation therapy, if end of therapy PET/CT report documents Deauville 3, 4, or 5 FDG avidity, to confirm complete response 	

Indication	Imaging Study
Surveillance after upfront therapy	 Imaging studies are only recommended when relapse is clinically suspected, because most individuals will clinically declare themselves and there is no survival advantage in pre-emptive imaging. Routine surveillance imaging is not supported in individuals without a prior history of recurrent disease.
Surveillance, individuals with recurrent HL and no evidence of disease following successful treatment	 ALL of the following, every 3 months for 1 year after completing therapy for recurrence: CT Neck with contrast (CPT® 70491) CT Chest with contrast (CPT® 71260) CT Abdomen and Pelvis with contrast (CPT® 74177)
Clarify inconclusive findings on conventional imaging suspicious for recurrence AND considering biopsy to establish recurrence	> PET/CT (CPT® 78815 or CPT® 78816)
Clinical symptoms suggesting recurrence	 MRI Brain with and without contrast (CPT® 70553) for known CNS involvement or new signs or symptoms suggesting intracranial disease AND either of the following: CT Neck (CPT® 70491), CT Chest (CPT® 71260), CT Abdomen/Pelvis (CPT® 74177) and, CT of other
	previously involved visceral areas or currently symptomatic areas OR PET/CT (CPT® 78815 or 78816)

- Most individuals experiencing recurrence are detected based on physical findings, and frequent CT surveillance imaging of Hodgkin lymphoma after completion of therapy does not improve post-recurrence overall survival. The primary determinant of survival at recurrence is time to relapse, regardless of whether relapse is detected clinically or via imaging. NCCN pediatric HL guidelines recommend no pre-emptive surveillance imaging.
- > Pediatric individuals have a high rate of neck involvement with Hodgkin lymphoma

Pediatric Oncology Imaging Guidelines

- ➤ Early treatment response evaluations involve both PET and CT as decisions about chemotherapy drug selection and radiation treatment are frequently made based on both anatomic (CT-based) and metabolic (PET/CT-based) responses.
- ➤ Indications and coding for rare circumstances where PET/MRI may be approved are found in PEDONC-1.4: PET Imaging in Pediatric Oncology

PEDONC-5.3: Pediatric Aggressive Mature B-Cell Non-Hodgkin Lymphomas (NHL)

Lympnomas (NHL)		
Indication	Imaging Study	
Initial staging	 CT Neck with contrast (CPT® 70491) May substitute MRI Neck with and without contrast (CPT® 70543) if requested CT Chest with contrast (CPT® 71260) CT Abdomen and Pelvis with contrast(CPT® 74177) May substitute MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) in place of CT Abdomen and Pelvis, if requested. Abdominal ultrasound (CPT® 76700 or 76705) may be approved at initial presentation if CT/MRI not available. CT with contrast or MRI without and with contrast any other symptomatic body area PET/CT (CPT® 78815 or CPT® 78816) (may be approved in addition to diagnostic CTs) 	
Additional initial staging if symptoms or extent of disease suggest intracranial extension or metastasis	➤ MRI Brain without and with contrast (CPT® 70553)	
Additional initial staging if symptoms or extent of disease suggest intraspinal extension or metastasis (back pain)	MRI of suspected spinal level involvement without and with contrast	
Restaging for treatment response (following initial response evaluation)	 As often as every cycle of chemotherapy (~every 3 weeks): CT with contrast or MRI without and with contrast (should be same modality as initial diagnosis if possible) of previously involved areas PET/CT (CPT® 78815) Whole body PET/CT (CPT® 78816) may be approved if there is clinical suspicion of, or known, skull or distal lower extremity involvement. PET/CT may be approved in conjunction with diagnostic CTs, PET/CT should not replace imaging with contrast-enhanced diagnostic-quality CT or MRI. 	

Indication	Imaging Study
Restaging for all subsequent treatment response, including end of therapy evaluation, after negative PET/CT (either Deauville or Lugano 1, 2 or 3 as reported in formal radiology interpretation)	CT with contrast or MRI without and with contrast (should be same modality as initial diagnosis if possible) of previously involved areas, as often as every 2 cycles of chemotherapy, and at the end of therapy
Assessment of disease activity in inconclusive residual masses seen on conventional imaging	> PET/CT (CPT® 78815 or CPT® 78816)
Individuals being treated with Rituximab who present with abdominal pain, due to risk of bowel perforation and obstruction	 CT Abdomen/Pelvis with contrast (CPT® 74177) US, x-ray, or other red flags are not required prior to CT
Surveillance of asymptomatic individuals with residual masses in the chest or abdomen and pelvis	Chest x-ray and Abdominal (CPT® 76700) and Pelvic (CPT® 76856) ultrasound 3 months after completion of therapy. If stable, no further imaging is indicated.
	MRI Brain with and without contrast (CPT® 70553) for history of CNS involvement or new signs or symptoms suggesting intracranial disease
Clinical symptoms or laboratory findings suggesting recurrence	And: ➤ CT of the Neck (CPT® 70491) and Chest (CPT® 71260) and CT Abdomen/Pelvis (CPT® 74177) and CT with contrast of other previously involved visceral areas or currently symptomatic areas ➤ PET/CT (CPT® 78815 or CPT® 78816) may be approved if relapse is suspected based on CT scan findings
Suspected PTLD recurrence with documentation of new palpable nodes, rising LDH, or rising quantitative EBV PCR	➤ PET/CT (CPT® 78815 or CPT® 78816)
Clarify inconclusive findings on conventional imaging to evaluate the need for biopsy to establish recurrence	> PET/CT (CPT® 78815 or CPT® 78816)

- Aggressive Mature B-Cell NHL includes all of the following diagnoses, all of which should be imaged according to this section:
 - Burkitt's lymphoma/leukemia (BL)
 - Diffuse Large B-Cell Lymphoma (DLBCL)
 - Primary Mediastinal Large B-Cell Lymphoma (PMBCL)
 - Post-transplant lymphoproliferative disorder (PTLD):
 - Most commonly occurs following solid organ or stem cell transplantation
 - Viral-associated lymphoproliferative disorders:
 - Most commonly occurs following hematopoietic stem cell transplantation or in individuals with primary immunodeficiency
- Initial treatment is usually 7 days of low intensity therapy, with early response evaluation determining next steps in therapy using CT with contrast or MRI without and with contrast of previously involved areas performed around Day 6.
 - Individuals are customarily still inpatient for this evaluation so outpatient requests should be rare for this time point.
- Routine asymptomatic surveillance with advanced imaging has not been found to impact outcomes as the majority of these individuals present clinically at relapse due to the highly aggressive nature of these lymphomas.
- Indications and coding for rare circumstances where PET/MRI may be approved are found in <u>PEDONC-1.4: PET Imaging in Pediatric Oncology</u>

PEDONC-5.4: Anaplastic Large Cell Lymphoma (ALCL)

Indication	Imaging Study
	 CT Neck/Chest/Abdomen/Pelvis (CPT® 70491, CPT® 71260, and CPT® 74177)
Initial staging	 MRI without and with contrast of affected area May be substituted for CT in cases of paraspinal or soft tissue extremity primary tumors
	 CT with contrast or MRI without and with contrast any other symptomatic body area
	> PET/CT (CPT® 78815 or CPT® 78816)
Additional initial staging for individuals with bony primary tumors or metastatic disease	Bone scan (See: PEDONC-1.3: Modality General Considerations)
Restaging at the end of induction chemotherapy (commonly 4 to 6 weeks)	 CT with contrast or MRI without and with contrast of previously involved areas (should be same modality as initial diagnosis if possible)
Treatment response in individuals treated with cytotoxic chemotherapy	 Every 2 cycles: CT of previously involved areas If CT is performed for primary treatment response, PET/CT (CPT® 78815 or 78816) can be approved to clarify inconclusive findings detected on conventional imaging OR PET/CT If PET/CT (CPT® 78815 or 78816) is performed for primary treatment response, CT or MRI can be approved to clarify inconclusive findings detected on PET imaging
Restaging after negative PET/CT (either Deauville or Lugano 1, 2 or 3 as reported in formal radiology interpretation)	 CT with contrast of previously involved areas
Surveillance	CT with contrast or MRI without and with contrast of all previously involved areas is indicated at 3, 6, 12, and 18 months after therapy is completed.

Indication	Imaging Study
Additional surveillance for individuals with bony primary tumors or metastatic disease	Bone scan (See: PEDONC-1.3: Modality General Considerations) is indicated at 3, 6, 12, and 18 months after therapy is completed
Clinical symptoms suggesting recurrence	CT Neck (CPT® 70491), Chest (CPT® 71260), Abdomen and Pelvis (CPT® 74177) and other previously involved or currently symptomatic areas
Clarify inconclusive findings on conventional imaging to evaluate the need for biopsy to establish recurrence	> PET/CT (CPT® 78815 or CPT® 78816)

- ➤ ALCL is similar in presentation to Hodgkin Lymphoma, and may be indistinguishable until immunocytology and molecular studies are complete
- ➤ Indications and coding for rare circumstances where PET/MRI may be approved are found in <u>PEDONC-1.4: PET Imaging in Pediatric Oncology</u>

PEDONC-6: Neuroblastoma		
PEDONC-6.1: Neuroblastoma - General Considerations	103	
PEDONC-6.2: Staging and Risk Grouping – Neuroblastoma	106	
PEDONC-6.3: Neuroblastoma - Initial Staging	109	
PEDONC-6.4: Neuroblastoma - Treatment Response Imaging (Risk		
Group Dependent) 111		
PEDONC-6.5: Neuroblastoma - Surveillance Imaging (Risk Group		
Dependent)	113	

PEDONC-6.1: Neuroblastoma - General Considerations

- <u>PEDONC-6</u> should be used to review neuroblastoma in individuals of all ages, with the exception of esthesioneuroblastoma in individuals of all ages, which should be reviewed using <u>ONC-3</u>.
- Neuroblastoma is divided into very low, low, intermediate, and high risk disease based on International Neuroblastoma Risk Group (INRG) Staging System (see: PEDONC-6.2: Staging and Risk Grouping). The treatment approaches for each risk group vary widely and have distinct imaging strategies. The risk group for a given individual should be provided by the ordering provider in the clinical information provided for review.
- ➤ For metabolic imaging in individuals who are MIBG positive at diagnosis and then become MIBG negative in response to treatment:

Continue to use MIBG (see: table below and <u>PEDONC-1.3</u> for coding)

 Continue to use MIBG (see: table below and <u>PEDONC-1.3</u> for coding) 	
Study Type	Coding
Bone scan	 Any of the following codes can be approved: CPT® 78300 CPT® 78305 CPT® 78306 CPT® 78803, 78830, or 78832 May be approved alone or in combination with: CPT® 78305 CPT® 78306
¹²³ - metaiodobenzylguanidine (MIBG) scintigraphy	 Any one of the following codes can be approved: CPT® 78801 CPT® 78802 CPT® 78804 Any one of the following codes may also be approved, individual or in combination with CPT® 78801,78802 or 78804 CPT® 78803 CPT® 78830 CPT® 78831 CPT® 78832 CPT® 78800 may be approved for KNOWN neuroblastoma when only a single site follow up is desired, but is not sufficient for the initial workup of suspected disease.

Study Type	Coding
Bone scan	 Any of the following codes can be approved: CPT® 78300 CPT® 78305 CPT® 78306 CPT® 78803, 78830, or 78832 May be approved alone or in combination with: CPT® 78305 CPT® 78306
Octreotide scan	Same coding as MIBG
Gallium scan	Same coding as MIBG

➤ MIBG remains the standard of care metabolic imaging in neuroblastoma, 18F-FDG PET/CT is not supported unless one of the exceptions below is present. All other radiotracers are considered investigational at this time:

radiotracers are considered investigational at this time:		
Indication	Imaging Study	
 ANY of the following: Individuals with MIBG-negativity documented at initial diagnosis At major decision points (such as hematopoietic stem cell transplant or surgery), if MIBG and CT/MRI findings are inconclusive 	 Whole body 18F-FDG PET/CT (CPT® 78816) Indications and coding for rare circumstances where PET/MRI may be approved are found in PEDONC-1.4: PET Imaging in Pediatric Oncology 	
 Individuals currently receiving medications that may interfere with MIBG uptake that cannot be safely discontinued prior to imaging, including: Tricyclic antidepressants (amitriptyline, imipramine, etc.) Selective serotonin reuptake inhibitors (SSRI's, sertraline, paroxetine, escitolapram, etc.) Neuroleptics (risperidone, haloperidol, etc.) Antihypertensive drugs (alpha or beta blockers, calcium channel blockers) Decongestants (phenylephrine, ephedrine, pseudoephedrine) Stimulants (methylphenidate, dextroamphetamine, etc.) 	 PET/CT (CPT® 78816) should only be approved for this indication when specific documentation of the medication interaction is included with the current PET imaging request. Indications and coding for rare circumstances where PET/MRI may be approved are found in PEDONC-1.4: PET Imaging in Pediatric Oncology 	

- Neuroblastoma is the most common extracranial solid tumor of childhood, and generally arises from the adrenal gland or along the sympathetic chain. Neuroblastoma staging has recently changed to better incorporate the prognostic impact of biological and genetic characteristics, particularly segmental chromosome aberrations (SCA) as an additional genomic marker. SCAs of 1p or 11g are poor prognostic indicators.
- 90 to 95% of neuroblastomas secrete homovanillic acid (HVA) and vannilylmandelic acid (VMA) in the urine, and Urine HVA/VMA should be performed at every disease evaluation for individuals with positive HVA or VMA at diagnosis
- 99mTc-MDP bone scan does not identify foci of disease that affect staging or clinical management and provides no advantage over MIBG scintigraphy and is not used for evaluation of most individuals with neuroblastoma

PEDONC-6.2: Staging and Risk Grouping - Neuroblastoma

- Most recent treatment protocols are using the rupdated International Neuroblastoma Risk Group (INRG) staging system
 - L1: Localized tumor not involving vital structures as defined by the list of imagedefined risk factors and confined to one body compartment
 - Image-defined risk factors include a list of specific imaging findings defining individuals less likely to be candidates for complete surgical resection
 - These risk factors involve the encasement of major blood vessels, airway, skull base, costovertebral junction, brachial plexus, spinal canal, or major organs or structures
 - ◆ L2: Locoregional tumor with presence of one or more image-defined risk factors
 - M: Distant metastatic disease (except stage MS)
 - MS: Metastatic disease in children younger than 18 months with metastases confined to skin, liver, and/or bone marrow with <10% involvement (MIBG must be negative in bone and bone marrow)

The tables for risk grouping are provided below for reference. The risk group for any given individual should be provided or documented by the requesting provider.

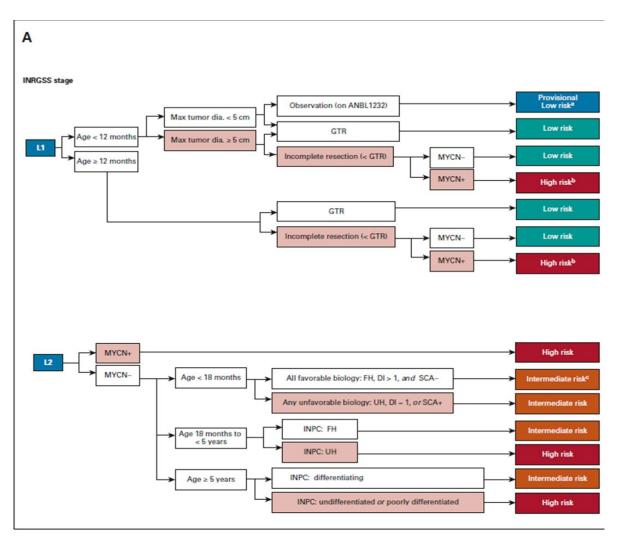

FIG. 1. Risk classifier v2 algorithm for patients with (A) locoregional and (B) metastatic tumors. (A) Patients with locoregional tumors with neuroblastoma and ganglioneuroblastoma (nodular) are classified based on INRG stage (L1 and L2), age, resection, biomarkers (*MYCN*, ploidy and SCAs), and INPC. Select patients with all favorable features are eligible for surveillance on the current non-high-risk COG ANBL1232 protocol L1 or L2 tumors with histopathology diagnostic category of ganglioneuroma or ganglioneuroblastoma-intermixed will be classified as low-risk regardless of biomarkers (and thus are not included in the figure). Ages are broken down by < 18 months, 18 months to < 5 years, and ≥ 5 years based on age categories used by INPC. ⁴If tumor progresses during observation, biopsy or resect and reclassify with biomarkers (as in COG ANBL1232). ⁴Consider complete resection if feasible. ⁴If no tumor burden symptoms, consider observation (as in COG ANBL1232). (B) Patient with metastatic tumors are classified by stage (M and MS), age, INPC, and biomarkers. For MS patients, presence or absence of symptoms may influence therapy independent of biomarker status. In previous risk classifiers, missing data were considered as unfavorable. In COG v2, missing data for SCA will not be considered as unfavorable based on the low incidence of SCA in otherwise favorable subsets. (continued on following page)

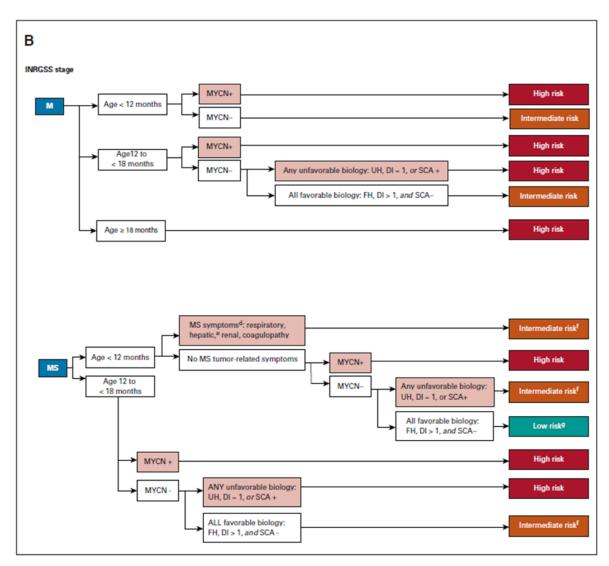

FIG 1. (Continued). Biopsy contraindicated, defer biopsy until stable (note: biomarker results may modify Risk Class). Hepatomegaly alone is an MS symptom in patients age < 3 months of age (see COG ANBL1232). Response-based therapy (as in COG ANBL1232). MS score-based therapy (as in COG ANBL1232). COG, Children's Oncology Group; DI, DNA index; dia., diameter; FH, favorable histology; GTR, gross-total resection; INPC, International Neuroblastoma Pathology Classifier; INRG, International Neuroblastoma Risk Group; MYCN+, MYCN amplified; MYCN-, MYCN not amplified; SCA, segmental chromosomal aberration; UH, unfavorable histology; v1, version 1; v2, version 2.

PEDONC-6.3: Neuroblastoma - Initial Staging

The following imaging studies should be considered appropriate in the initial staging of individuals with Neuroblastoma:

Indication	Imaging Study
Initial staging for all individuals	 123I-metaiodobenzylguanidine (see table in PEDONC-6.1: Neuroblastoma – General Considerations for MIBG coding details) scintigraphy
	AND
	 ONE of the following sets of imaging: CT Neck/Chest/Abdomen/Pelvis with contrast (CPT® 70491, 71260, and 74177) OR MRI Neck/Chest/Abdomen/Pelvis without and with contrast (CPT® 70543, CPT® 71552, CPT® 74183, and CPT® 72197)
Evaluation of paraspinal tumors where cord compression is a possibility	MRI without and with contrast of the appropriate spinal level
Evaluation of suspected adrenal neuroblastoma, ganglioneuroblastoma, or ganglioneuroma when CT or MRI is inconclusive for an adrenal lesion.	 Adrenal nuclear imaging (CPT[®] 78075)
Clinical signs/symptoms suggest brain involvement	 MRI Brain without and with contrast (CPT[®] 70553)

PET should not be used unless one of the exceptions stated in section <u>PEDONC-6.1: Neuroblastoma - General Considerations</u> is present

- MIBG provides superior sensitivity and sensitivity for detecting viable osseous disease compared with bone scintigraphy so technetium bone scan is not necessary when MIBG is utilized. MIBG is positive in 90 to 95% of neuroblastomas.
 - Most MIBG imaging studies are SPECT/CT studies using CT for localization only.
 Separate diagnostic CT codes should not be approved for this purpose
 - Occasionally MIBG cannot be performed prior to initiation of therapy. In this
 circumstance, MIBG should be completed within 3 weeks of therapy initiation as
 the reduction in MIBG avidity in response to chemotherapy is not immediate.
 Inability to complete MIBG before starting therapy is not an indication to approve
 PET imaging

Pediatric Oncology Imaging Guidelines

MRI Brain of asymptomatic individuals with no history of brain metastases is not indicated for neuroblastoma but may be approved for signs and symptoms of brain involvement.

<u>PEDONC-6.4: Neuroblastoma - Treatment Response Imaging (Risk</u> Group Dependent)

Risk Grouping will not be known at the time of initial staging, but is critical for all imaging decisions after initial staging is complete. The treating oncologist should always know the individual's risk grouping. It is not possible to establish the appropriate imaging plan for a neuroblastoma individual without knowing his/her risk group.

All Very Low Risk and Low Risk Neuroblastoma Not Receiving Chemotherapy:

Indication	Imaging Study
All individuals, 6 to 8 weeks after	 CT with contrast or MRI without and with contrast of the primary tumor site
diagnosis to determine if additional treatment is necessary	 With contrast of the primary turnor site Ultrasound may be used in
a dament is necessary	place of CT or MRI to avoid
	radiation and/or anesthesia
	exposure in low risk individuals

Background and Supporting Information

Many individuals will be treated with surgical resection only without adjuvant therapy, and these individuals enter immediately into surveillance.

All Intermediate Risk Neuroblastoma and Very Low Risk or Low Risk Neuroblastoma Receiving Chemotherapy:

Neurobiastoma Necelving Chemotherapy.	
Indication	Imaging Study
Prior to surgical resection	 Restaging imaging (MIBG and CT or MRI, as performed at initial diagnosis)
Treatment response, as often as every 2 cycles of chemotherapy (~every 6 weeks and	CT Chest/Abdomen/Pelvis with contrast (CPT® 71260, and CPT® 74177)
at the end of planned treatment)	OR
	MRI Chest/Abdomen/Pelvis without and with contrast, (CPT® 71552, CPT® 74183, and CPT® 72197)
	AND
	 CT or MRI of other sites with prior measurable disease
In addition to treatment response listed	MIBG scan (see table in PEDONC-6.1:
above, every 4 cycles, and at the end of	Neuroblastoma – General
planned chemotherapy treatment	<u>Considerations</u> for MIBG coding details)

- Individuals generally receive 2 to 12 cycles of moderate-intensity chemotherapy depending on response to treatment.
- Surgical resection may occur prior to or following chemotherapy depending on disease stage. Restaging prior to surgery is appropriate.

High Risk Neuroblastoma:

Indication	Imaging Study
 ANY of the following: Treatment response As often as every 2 cycles of chemotherapy, mAb, or biologic therapy (~every 6 weeks) Change in modality Prior to surgery, HSCT, XRT, or mAb therapy End of therapy 	 CT Chest/Abdomen/Pelvis with contrast (CPT® 71260, and CPT® 74177) OR MRI Chest/Abdomen/Pelvis without and with contrast, (CPT® 71552, CPT® 74183, and CPT® 72197) AND CT or MRI of other sites with prior measurable disease
	 MIBG scan (see table in <u>PEDONC-6.1: Neuroblastoma – General</u> <u>Considerations</u> for MIBG coding details)
At completion of ¹³¹ I-MIBG therapy	 123I-MIBG scan FDG-PET cannot be used after 131I-MIBG therapy
Preoperative planning	More frequent imaging with any of the above modalities can be approved around the time of surgery if needed

Background and Supporting Information

This group of individuals receives highly aggressive therapy using sequential chemotherapy, surgery, high dose chemotherapy with stem cell rescue, radiotherapy, monoclonal antibody (mAb) immunotherapy, and biologic therapy.

PEDONC-6.5: Neuroblastoma - Surveillance Imaging (Risk Group Dependent)

Very Low Risk and Low Risk Neuroblastoma:

Indication	Imaging Study
All individuals	 CT with contrast or MRI without and with contrast of the primary tumor site 3, 6, 9, 12, 18, 24, and 36 months after surgery. If negative at 36 months, no further advanced imaging is necessary.
Clarification of findings on CT or MRI suspicious for disease recurrence	 MIBG (see table in <u>PEDONC-6.1:</u> <u>Neuroblastoma – General</u> <u>Considerations</u> for MIBG coding details)

Intermediate Risk Neuroblastoma:

Indication	Imaging Study
All individuals	 CT with contrast or MRI without and with contrast of the primary tumor site and known metastatic sites at 3, 6, 9, 12, 18, 24, and 36 months after completion of therapy. If negative at 36 months, no further advanced imaging is necessary. Ultrasound may be sufficient to evaluate the primary tumor site for certain individuals and may be approved if requested to replace CT or MR
 BOTH of the following: Individuals with stage 4, or M disease, or 4S, or MS disease AND Positive MIBG at completion of therapy 	 MIBG scan (see table in PEDONC-6.1: Neuroblastoma – General Considerations for MIBG coding details) at 3, 6, 9, 12, 24, and 36 months after completion of therapy. If negative at 36 months, no further MIBG imaging is necessary. MIBG (or PET, if MIBG-negative at
	initial diagnosis) not indicated for all other intermediate risk individuals

Pediatric Oncology Imaging Guidelines

High Risk Neuroblastoma:

Indication	Imaging Study
All individuals	 CT with contrast or MRI without and with contrast of the primary tumor site at 3, 6, 9, 12, 18, 24, 30, 36, 42, 48, 54, and 60 months, then annually until 10 years after completion of therapy. If negative at 10 years, no further advanced imaging is necessary.
	 MIBG scan (see table in <u>PEDONC-6.1: Neuroblastoma – General Considerations</u> for MIBG coding details) at 3, 6, 9, 12, 18, 24, 30, and 36 months after completion of therapy. If negative at 36 months, no further MIBG or PET imaging is necessary.
Suspected recurrence	CT Chest/Abdomen/Pelvis with contrast (CPT® 71260, and CPT® 74177) or MRI Chest/Abdomen/Pelvis without and with contrast, (CPT® 71552, CPT® 74183, and CPT® 72197) and other sites of prior measurable disease or current symptoms
	 MRI Brain with and without contrast (CPT[®] 70553) for signs or symptoms of brain involvement
	 MIBG scan (see table in <u>PEDONC-6.1: Neuroblastoma – General Considerations</u> for MIBG coding details)

- Very Low Risk and Low Risk Neuroblastoma:
 - Urine HVA/VMA (if positive at diagnosis) at 1, 2, 3, 6, 9, 12, 18, 24, 36, 48, and 60 months after surgery
 - CT Chest is not indicated in asymptomatic surveillance imaging of neuroblastoma individuals with no prior history of thoracic disease
- Intermediate Risk Neuroblastoma:
 - Urine HVA/VMA (if positive at diagnosis) every month until 12 months after completion of therapy, then at 14, 16, 18, 21, 24, 30, and 36 months after completion of therapy, and then annually until 10 years after completion of therapy
- High Risk Neuroblastoma:
 - Urine HVA/VMA (if positive at diagnosis) at 3, 6, 9, 12, 18, 24, 30, 36, 42, 48, 54, and 60 months after completion of therapy, then annually until 10 years after completion of therapy, and for suspected recurrence.
 - Early detection of recurrence with ¹²³I-MIBG has been shown to improve postrelapse outcomes in high risk neuroblastoma

PEDONC-7: Pediatric Renal Tumors	
PEDONC-7.1: Pediatric Renal Tumors General Considerations	118
PEDONC-7.2: Unilateral Wilms Tumor (UWT)	119
PEDONC-7.3: Bilateral Wilms Tumor (BWT)	122
PEDONC-7.4: Pediatric Renal Cell Carcinoma (RCC)	125
PEDONC-7.5: Clear Cell Sarcoma of the Kidney (CCSK)	
PEDONC-7.6: Malignant Rhabdoid Tumor of the Kidney (MRT) a	nd
Other Extracranial Sites	129
PEDONC-7.7: Congenital Mesoblastic Nephroma (CMN)	131

PEDONC-7.1: Pediatric Renal Tumors General Considerations

- A variety of tumors can occur in the pediatric kidney, and include the following:
 - Wilms Tumor
 - Favorable histology (FHWT)
 - Focal anaplasia (FAWT)
 - Diffuse anaplasia (DAWT)
 - Bilateral Wilms Tumor (BWT)
 - Renal Cell Carcinoma (RCC)
 - Clear Cell Sarcoma of the Kidney (CCSK)
 - Malignant Rhabdoid Tumor of the Kidney (MRT)
 - Congenital Mesoblastic Nephroma (CMN)
 - Other Cancers occurring in the Kidney:
 - Neuroblastoma
 - Primitive Neuroectodermal Tumor
 - Rhabdomyosarcoma
 - Non-Rhabdomyosarcoma Soft Tissue Sarcomas
 - These and other rare tumors have been reported occurring primarily in the kidney and should be imaged according to the guidelines for the specific histologic diagnosis
- For suspected renal tumor, cell type unknown, image according to <u>PEDONC-7.4:</u> <u>Pediatric Renal Cell Carcinoma (RCC)</u>
- PET is not routinely supported for initial staging, treatment response or surveillance of any pediatric renal tumor.

PEDONC-7.2: Unilateral Wilms Tumor (UWT)

Indication	Imaging Study
Initial Staging	 CT Abdomen with contrast (CPT® 74160) CT Abdomen and Pelvis with contrast (CPT® 74177) may be approved in lieu of CPT® 74160 included if mass is presumed to extend into the pelvis. Doppler ultrasound to evaluate for tumor thrombus is not necessary unless CT findings are inconclusive CT Chest with (CPT® 71260) or without contrast (CPT® 71250) Should be completed prior to anesthesia exposure if possible
Bilateral renal lesions	 PET is not routinely indicated in the initial staging of any pediatric renal tumor MRI Abdomen (CPT® 74183) and Pelvis (CPT®
noted on ultrasound or CT Additional initial staging imaging for any individual with neurologic signs or symptoms raising suspicion of CNS metastases	72197) without and with contrast MRI Brain without and with contrast (CPT® 70553)
Additional initial staging imaging for any patient with signs or symptoms raising suspicion of bony metastases	> Bone scan (see: PEDONC-1.3 for coding)
Treatment response ~every 2 cycles during treatment and at the end of planned therapy	 CT Chest with (CPT® 71260) or without contrast (CPT® 71250) CT Abdomen with contrast (CPT® 74160) or CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen (CPT® 74183) and Pelvis (CPT® 72197) without and with contrast
Rare circumstances to establish the presence of active disease only when a major therapeutic decision depends on PET avidity	> PET/CT (CPT® 78815)
Surveillance, very low risk FHWT treated with nephrectomy only	 At months 3, 6, 12, and 18 months after nephrectomy: CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250), or chest x-ray AND

Indication	Imaging Study
	 CT Abdomen and Pelvis with contrast (CPT® 74177) or Abdominal and Pelvic US (CPT® 76700, and CPT® 76856 if requested) At months 9, 15, 21 after nephrectomy: Abdominal Ultrasound (CPT® 76700 and 76506) AND Chest x-ray Every 3 months, from month 24 to month 30 after nephrectomy: Abdominal Ultrasound (CPT® 76700) and Chest x-ray After month 30, every 6 months up to 5 years off therapy: Abdominal Ultrasound (CPT® 76700)
Surveillance, FHWT treated with chemotherapy with or without XRT	 At months 6, 12, 18, 24, 30, and 36 months after completion of all therapy: CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250), or CXR and CT Abdomen with contrast (CPT® 74177), MRI Abdomen without and with contrast (CPT® 74183), or Abdominal US (CPT® 76700) At months 3, 9, 15, 21, 27, and 33 after completion of all therapy: Abdominal Ultrasound (CPT® 76700) and CXR After month 36, every 6 months up 5 years off therapy: Abdominal Ultrasound (CPT® 76700) Pelvic imaging is not indicated for surveillance unless prior pelvic involvement has been documented or there was tumor rupture at diagnosis
Surveillance, FAWT or DAWT treated with chemotherapy with or without XRT	 At months 3, 6, 9, 12, 15, 18, 21, and 24 after completion of all therapy: CT Chest with (CPT® 71260) or without contrast (CPT® 71250) and CT Abdomen and Pelvis with contrast (CPT® 74177), MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197), or Abdominal US (CPT® 76700) Every 3 months, from months 27 through 60: Abdominal US and CXR
Surveillance, stage III or IV	 At months 3, 6, 9, 12, 18 and 24 months after completion of all therapy: CT Abdomen with contrast (CPT[®] 74160)

Indication	Imaging Study
	 CT Abdomen and Pelvis with contrast (CPT® 74177) may be substituted if history of pelvic disease or pelvic signs and symptoms) CT Chest with (CPT® 71260) or without contrast (CPT® 71250)
	 At months 15, 21, 30, 36, 42, 48, and 60 Abdominal US (CPT® 76700) and CXR
Surveillance, recurrent unilateral Wilms tumor	 At months 3, 6, 9, and 12 after completing therapy for recurrence: CT of the Chest/Abdomen/Pelvis (CPT[®] 71260
	 and CPT® 74177) Surveillance imaging later than 12 months after completing therapy for recurrence should follow the
 There are no data to supple 	standard timing listed in this surveillance section oort the use of PET imaging for routine surveillance in

any patient with Wilms tumor.

- Many individuals will present with an asymptomatic abdominal mass and will undergo ultrasound as a primary evaluation.
- ➤ Only ~0.5% of individuals with Wilms tumor will ever develop brain metastases
- The majority of individuals will receive chemotherapy with or without XRT, beginning within 14 days of initial surgery

PEDONC-7.3: Bilateral Wilms Tumor (BWT)

Initial Staging MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) CT Abdomen and Pelvis with contrast (CPT® 74177) may be approved in lieu of MRI per provider request. CT Abdomen and Pelvis with contrast (CPT® 74177) may be approved in lieu of MRI per provider request. CT Abdomen and Pelvis with contrast (CPT® 74177) is often performed prior to discovery of bilateral lesions and should not prevent MRI from being approved if requested Doppler ultrasound to evaluate for tumor thrombus is not necessary unless CT findings are inconclusive CT Chest with (CPT® 71260) or without contrast (CPT® 71250) Should be completed prior to anesthesia exposure if possible PET is not indicated in the initial staging of any pediatric renal tumor Additional initial staging imaging for any individual with neurologic signs or symptoms raising suspicion of CNS metastases Additional initial staging imaging for any individual with signs or symptoms raising suspicion of bony metastases Treatment response every 2 cycles during treatment and at the end of planned therapy MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) CT Abdomen and Pelvis without and with contrast (CPT® 74177) may be used for patients with a contraindication to MRI CT Chest with (CPT® 71260) or without contrast (CPT® 71250) PET/CT (CPT® 78815)	PEDONC-7.3. Bilateral V	
(CPT® 74183 and CPT® 72197) CT Abdomen and Pelvis with contrast (CPT® 74177) may be approved in lieu of MRI per provider request. Surveillance, stage For II At months 6, 12, 18, 24, 30, and 36 after completion of all therapy:	establish the presence of active disease only when a major therapeutic decision	 At months 6, 12, 18, 24, 30, and 36 after completion

Imaging Study
CT Chest with (CPT® 71260) or without contrast CPT® 71250) onths 3, 6, 12, 18, 24, 30, and 36 after pletion of all therapy: CT Abdomen with contrast (CPT® 74160), MRI abdomen without and with contrast (CPT® 4183), or Abdominal US (CPT® 76700) onths 9, 15, 21, 27, 33, 39, 42, 45, 48, 51, 54, and 60 after completion of all therapy: abdominal US (CPT® 76700) ic imaging is not indicated for surveillance as prior pelvic involvement has been amented or there was tumor rupture at diagnosis reillance imaging after month 36: abdominal US (CPT® 76700) every 3 months antil age 8 CXR reillance imaging with CT of the ast/Abdomen/Pelvis (CPT® 71260 and CPT® 77) following successful treatment for recurrent eral Wilms tumor can be approved every 3 this for 1 year after completing therapy for recurrence. Surveillance imaging later than 12 months after completing therapy for recurrence should follow the standard timing listed in this surveillance ection. onths 3, 6, 9, 12, 18 and 24 after completion of the apy: CT Abdomen/Pelvis with contrast (CPT® 74160) CT Abdomen/Pelvis with contrast (CPT® 74177) may be substituted if history of pelvic
disease or pelvic signs and symptoms CT Chest with (CPT® 71260) or without contrast CPT® 71250)
onths 15, 21, 30, 36, 42, 48 and 60 after pletion of all therapy: CXR Abdominal US (CPT® 76700)

Wilms tumor.

- Many individuals will present with an asymptomatic abdominal mass and will undergo ultrasound as a primary evaluation.
- Individuals with bilateral Wilms Tumor may begin therapy without a histologic diagnosis to preserve a localized disease stage and attempt to shrink the tumors to allow for renal-sparing surgical approaches
- ➤ Only ~0.5% of Wilms Tumor individuals will ever develop brain metastases

PEDONC-7.4: Pediatric Renal Cell Carcinoma (RCC)

PEDONC-7.4: Pediatric Re	PEDONC-7.4: Pediatric Renal Cell Carcinoma (RCC)	
Indication	Imaging Study	
Initial Staging	 CT Abdomen and Pelvis with contrast (CPT® 74177) If bilateral renal lesions are noted on ultrasound or CT, MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) should be strongly considered CT Chest with (CPT® 71260) or without contrast (CPT® 71250) Should be completed prior to anesthesia exposure if possible PET scan is not indicated in the initial staging of any pediatric renal tumor 	
Additional initial staging for any patient with neurologic signs or symptoms raising suspicion of CNS metastases	MRI Brain without and with contrast (CPT® 70553)	
Additional initial staging for any patient with signs or symptoms raising suspicion of bony metastases	➤ Bone scan (See: <u>PEDONC-1.3</u> for coding)	
Treatment response in patients with residual measurable disease after initial surgery and receiving adjuvant medical therapy	 Every 2 cycles during active treatment: CT Chest with (CPT® 71260) or without contrast (CPT® 71250) and CT Abdomen with contrast (CPT® 74160) Pelvic imaging is not indicated unless prior pelvic involvement has been documented 	
Rare circumstances to establish the presence of active disease only when a major therapeutic decision depends on PET avidity	 PET/CT (CPT® 78815) Indications and coding for rare circumstances where PET/MRI may be approved are found in PEDONC-1.4: PET Imaging in Pediatric Oncology 	
Surveillance in individual with documented CNS metastases	 Every 6 months for 2 years after completion of all therapy: MRI Brain without and with contrast (CPT® 70553) 	
Surveillance in individuals with TFE3 or TFEB subtype	 Every 3 months for 2 years, then every 6 months for 2 years after completion of all therapy: CT Chest with (CPT® 71260) or without contrast (CPT® 71250) CT Abdomen with contrast (CPT® 74160) or MRI Abdomen without and with contrast (CPT® 74183) Pelvic imaging is not indicated for surveillance unless prior pelvic involvement has been documented 	
Surveillance in all other	> See: ONC-17.4: Renal Cell Cancer (RCC) -	
histologies	Surveillance	
New signs/symptoms suggestive of CNS recurrence	MRI Brain without and with contrast (CPT® 70553)	
> PET is not routinely utilized to	assess treatment response in pediatric RCC.	

- A majority of pediatric cases have a novel subtype involving TFE3 or TFEB translocations, which have a different natural history than "adult type" RCC
- Individuals of any age with TFE3 or TFEB translocated RCC should be imaged according to this guideline section
- ➤ 40 to 45% of pediatric RCC cases have similar histologies to adult RCC (clear cell, papillary, chromophobe, etc.) and imaging decisions will be similar to general oncology guidelines.
 - Individuals with all other subtypes of RCC should be imaged according to <u>ONC-17: Renal Cell Cancer (RCC)</u> in the Oncology Imaging Guidelines
- Many individuals will present with an asymptomatic abdominal mass and will undergo ultrasound as a primary evaluation. Doppler ultrasound to evaluate for tumor thrombus is no longer necessary unless CT findings are inconclusive, and should not be performed if CT is already completed
- Most individuals will have surgical resection of all disease at the time of diagnosis and will enter directly into surveillance

PEDONC-7.5: Clear Cell Sarcoma of the Kidney (CCSK)

Be careful not to confuse the diagnosis with clear cell RCC. See: ONC-17: Renal Cell Cancer (RCC) for imaging guidelines.

	Renai Cell Cancer (RCC) for imaging guidelines.	
Indication	Imaging Study	
Initial Staging	 CT Abdomen and Pelvis with contrast (CPT® 74177) Doppler ultrasound to evaluate for tumor thrombus is not necessary unless CT findings are inconclusive CT Chest with (CPT® 71260) or without contrast (CPT® 71250) Should be completed prior to anesthesia exposure if possible Bone scan (see: PEDONC-1.3 for coding) MRI Brain without and with contrast (CPT® 70553) PET is not indicated in the initial staging of any pediatric renal tumor 	
Bilateral renal lesions are noted on ultrasound or CT in initial staging	MRI Abdomen and Pelvis without and with contrast	
Treatment response ~every 2 cycles during treatment and at the end of planned therapy	 CT Chest with (CPT® 71260) or without contrast (CPT® 71250) CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) Additionally, for patients with CNS metastases at initial staging: MRI Brain without and with contrast (CPT® 70553) Bone scan (see: PEDONC-1.3 for coding) at the end of planned therapy 	
Rare circumstances to establish the presence of active disease only when a major therapeutic decision depends on PET avidity	 PET/CT (CPT® 78815) Indications and coding for rare circumstances where PET/MRI may be approved are found in PEDONC-1.4: PET Imaging in Pediatric Oncology 	
Surveillance	 Every 3 months for 2 years after completion of all therapy: CT Chest with (CPT® 71260) or without contrast (CPT® 71250) CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) Every 6 months for 3 years after completion of all therapy: MRI Brain without and with contrast (CPT® 70553) Every 3 months for 1 year, then every 6 months for 2 years after completion of all therapy: Bone scan (see: PEDONC-1.3 for coding) If negative at 36 months, no further advanced imaging is necessary. Other surveillance imaging should be by Abdominal US (CPT® 76700) and chest x-ray 	

Pediatric Oncology Imaging Guidelines

Background and Supporting Information

Many individuals will present with an asymptomatic abdominal mass and will undergo ultrasound as a primary evaluation. Doppler ultrasound to evaluate for tumor thrombus is no longer necessary unless CT findings are inconclusive, and should not be performed if CT is already completed

PEDONC-7.6: Malignant Rhabdoid Tumor of the Kidney (MRT) and Other Extracranial Sites

Be careful not to confuse the diagnosis with rhabdomyosarcoma. See: PEDONC-8.2: Rhabdomyosarcoma (RMS) for Imaging Guidelines

Indication	Imaging Study
Initial Staging	 CT Abdomen and Pelvis with contrast (CPT® 74177) Doppler ultrasound to evaluate for tumor thrombus is not necessary unless CT findings are inconclusive CT Chest with (CPT® 71260) or without contrast (CPT® 71250) Should be completed prior to anesthesia exposure if possible
	➤ Bone scan (see: <u>PEDONC-1.3</u> for coding)
	 MRI Brain without and with contrast (CPT® 70553)
	PET is not indicated in the initial staging of any pediatric renal tumor
Bilateral renal lesions are noted on ultrasound or CT in initial staging	MRI Abdomen and Pelvis without and with contrast
Treatment response ~every 2 cycles during treatment and at the end of	 CT Chest with (CPT[®] 71260) or without contrast (CPT[®] 71250)
planned therapy	 CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) If primary site other than kidney, perform CT with contrast or MRI without and with contrast of primary site in place of abdominal and pelvic imaging
>	 MRI Brain without and with contrast (CPT® 70553) can be performed: Every 2 cycles during treatment for patients with CNS metastases at initial staging At the end of planned therapy for all patients
	Bone scan (see: <u>PEDONC-1.3</u> for coding) at the end of planned therapy only if positive at initial diagnosis
Rare circumstances to establish the presence of active disease only when a	 PET/CT (CPT® 78815) Indications and coding for rare circumstances where PET/MRI may be approved are found in PEDONC-1.4: PET Imaging in Pediatric Oncology

Indication	Imaging Study
major therapeutic decision depends on PET avidity	
Surveillance	 Every 3 months for 2 years after completion of all therapy: CT Chest with (CPT® 71260) or without contrast (CPT® 71250)
	 Every 3 months for 3 years after completion of all therapy: CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) If primary site other than kidney, perform CT with contrast or MRI without and with contrast of primary site in place of abdominal imaging
	 Every 3 months for 1 year, then every 6 months for 1 year after completion of all therapy: MRI Brain without and with contrast (CPT® 70553)
	 If bone scan positive at initial diagnosis: Every 3 months for 1 year, then every 6 months for 2 years: Bone scan (see: PEDONC-1.3 for coding) If negative at 36 months, no further advanced imaging is necessary
	The role of surveillance imaging beyond these timeframes in unclear. Abdominal US (CPT® 76700) and chest x-ray may be considered
Continued Surveillance of patients with Rhabdoid Tumor predisposition Syndrome	See: PEDONC-2.11: Rhabdoid Tumor Predisposition Syndrome

- MRT is a highly aggressive histologic variant that can also occur in other locations and all non-CNS sites should follow these guidelines
- Primary CNS rhabdoid malignancies should be imaged according to <u>PEDONC-4.5:</u> <u>Atypical Teratoid/Rhabdoid Tumors (ATRT)</u>
- Many individuals will present with an asymptomatic abdominal mass and will undergo ultrasound as a primary evaluation.

PEDONC-7.7: Congenital Mesoblastic Nephroma (CMN)

Congenital Mesoblastic Nephroma Initial Staging:

- ➤ CT Abdomen and Pelvis with contrast (CPT® 74177)
- ➤ CT Chest with (CPT® 71260) to evaluate inconclusive findings on chest x-ray

Congenital Mesoblastic Nephroma Treatment Response:

- CT Abdomen and Pelvis with contrast (CPT® 74177) once following resection to establish baseline imaging, and those with a complete resection should then be imaged according to surveillance guidelines
- CT Abdomen and Pelvis with contrast (CPT® 74177) for individuals receiving preoperative chemotherapy every 2 cycles until surgery and then should be imaged according to surveillance guidelines after their postoperative baseline imaging study

Congenital Mesoblastic Nephroma Surveillance Imaging:

- Ultrasound is the preferred surveillance imaging modality to avoid radiation and anesthesia exposures
- CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) for residual abnormalities present on post-operative imaging or inconclusive findings on ultrasound every 3 months for 1 year after completion of all therapy

- This is the most common primary renal tumor occurring in young infants, and the overall prognosis is very good
- Complete surgical removal is curative in most cases, and histologically confirmed metastatic disease or bilateral disease has never been reported
- Many individuals will present with an asymptomatic abdominal mass at the time of birth or abnormal prenatal ultrasound and will undergo ultrasound as a primary evaluation
- > PET is not indicated in the initial staging of any pediatric renal tumor
- > Recurrences are rare, but most occur within 12 months of diagnosis

PEDONC-8: Pediatric Soft Tissue Sarcomas	
PEDONC-8.1: Pediatric Soft Tissue Sarcomas – General	
Considerations	134
PEDONC-8.2: Rhabdomyosarcoma (RMS)	135
PEDONC-8.3: Non-Rhabdomyosarcoma Soft Tissue Sarcomas	
(NRSTS)	138

<u>PEDONC-8.1: Pediatric Soft Tissue Sarcomas – General</u> Considerations

- Unless specified below, individuals age <18 years old should be imaged according to this guideline section. Exceptions include:
 - Rhabdomyosarcoma individuals of all ages should be imaged according to guidelines in PEDONC-8.2: Rhabdomyosarcoma (RMS)
 - Kaposi's sarcoma individuals of all ages should be imaged according to guidelines in <u>ONC-31.10: Kaposi's Sarcoma</u> in the Oncology Imaging Guidelines
- Evaluation of soft tissue masses of uncertain nature prior to biopsy should follow general imaging guidelines:
 - Individuals age 0 to 17 years, see: <u>PEDMS-3: Soft Tissue and Bone Masses</u> in the Pediatric Musculoskeletal Imaging Guidelines
 - Individuals age ≥18 years, see: MS-10: Soft Tissue Mass or Lesion of Bone in the Musculoskeletal Imaging Guidelines
- Where there are indications for PET/CT in these guidelines, note that indications and coding for rare circumstances where PET/MRI may be approved are found in PEDONC-1.4: PET Imaging in Pediatric Oncology

PEDONC-8.2: Rhabdomyosarcoma (RMS)

Individuals of all ages are imaged according to this guideline, with exception of uterine rhabdomyosarcoma, which is imaged according to <u>ONC-12: Sarcomas –</u> <u>Bone, Soft Tissue and GIST</u>.

Rhabdomyosarcoma Initial Staging:

- CT with contrast or MRI without and with contrast for primary site imaging of RMS arising in the abdomen or pelvis
- CT Chest with (CPT® 71260) or CT Chest without contrast (CPT® 71250) to evaluate for lung metastases in the initial workup of all pediatric soft tissue sarcomas and should be completed prior to anesthesia exposure if possible
- > Other staging imaging should be deferred until a histologic diagnosis is made
- ➤ Whole body PET/CT (CPT® 78816) is the preferred study for initial staging of RMS
- Bone scan (See: <u>PEDONC-1.3</u> for coding) may be substituted for PET imaging if PET not available
- CT Abdomen and Pelvis with contrast (CPT® 74177) for initial metastatic staging of pediatric RMS only in the following situations:
 - Evaluation of inconclusive PET findings
 - Primary site of abdomen or pelvis
 - Lower extremity primary sites
- MRI Brain (CPT® 70553) and Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) for initial staging of pediatric RMS only in the following situations:
 - Primary site involving the paraspinal or paravertebral region
 - ◆ PET- or bone scan-avid lesions in skull, neck, vertebrae
 - Neurologic signs or symptoms raising suspicion of CNS metastases

Rhabdomyosarcoma Treatment Response:

- CT Chest with (CPT® 71260) or CT Chest without contrast (CPT® 71250) every 2 cycles during treatment and at the end of planned therapy
- Primary site imaging:
 - CT with contrast or MRI without and with contrast every 2 cycles during treatment and at the end of planned therapy
 - Restaging imaging after local control surgery (complete or partial resection) is completed
- Metastatic site imaging:
 - Repeat imaging of all known metastatic sites using the same modality as during initial staging whenever primary site imaging is necessary

- > PET to assess treatment response in RMS only in the following rare circumstances:
 - Assessment prior to local control surgery or radiation therapy.
 - Evaluation of residual mass visible on conventional imaging as part of end of therapy evaluation
 - Assessment of disease visible on PET but not conventional imaging
 - Once PET has been documented to be negative for a given individual's cancer or all PET-avid disease has been surgically resected, PET should not be used for continued disease monitoring or surveillance unless one of the exceptions in section <u>PEDONC-1: General Guidelines</u> applies.
 - PET may be appropriate when results are likely to result in a treatment change for the individual, including a change from active treatment to surveillance.

Rhabdomyosarcoma Surveillance Imaging:

- All individuals with localized RMS:
 - CT with or MRI without and with contrast of primary tumor site every 3 months for 1 year, then every 4 months for 2 years, then every 6 months for 1 year after completion of all therapy
 - Chest x-ray every 3 months for 1 year, then every 4 months for 2 years, then
 every 6 months for 1 year after completion of all therapy
 - CT Chest with (CPT® 71260) or CT Chest without contrast (CPT® 71250) for new or worsening clinical symptoms of chest disease or new findings on chest x-ray
- All individuals with metastatic RMS:
 - CT with contrast or MRI without and with contrast of primary tumor site every 3
 months for 1 year, then every 4 months for 2 years, then every 6 months for 1
 year after completion of all therapy
 - CT Chest with (CPT® 71260) or CT Chest without contrast (CPT® 71250) and all known metastatic sites every 3 months for 1 year, then every 4 months for 2 years, then every 6 months for 1 year after completion of all therapy
 - Nuclear bone scan (See: <u>PEDONC-1.3</u> for coding) for surveillance of known bony metastases every 3 months for 1 year, then every 4 months for 2 years, then every 6 months for 1 year after completion of all therapy
- PET for surveillance imaging of RMS only when one of the following applies:
 - Conventional imaging (CT, MRI, US, plain film) reveals findings that are inconclusive or suspicious for recurrence, and PET avidity will determine whether biopsy or continued observation is appropriate
 - Rare circumstances where obvious clinical symptoms show strong evidence suggesting recurrence, and PET would replace conventional imaging modalities.

- Soft tissue sarcomas occur in both adult and pediatric individuals, but some are more common in one age group than the other.
- Pediatric soft tissue sarcomas are divided into two groups:
 - Rhabdomyosarcoma (RMS) accounts for ~60% of soft tissue sarcomas in young individuals, but only ~25% of soft tissue sarcomas in adolescents
 - Nonrhabdomyosarcoma soft tissue sarcomas (NRSTS) which encompasses all other histologic subtypes
- Because RMS can arise from any muscle tissue, the presenting symptoms and primary tumor sites vary widely and strongly influence the appropriate imaging decisions
- CT with contrast is the preferred primary site imaging modality for RMS arising in the thoracic cavity (not the chest wall)
- MRI without and with contrast is the preferred primary site imaging modality for RMS occurring in all other anatomic locations, including the chest wall
- PET/CT is superior to conventional imaging for detection of nodal and bony metastases in pediatric RMS and is indicated in the initial staging of all individuals after histologic diagnosis is established
- CT Abdomen and Pelvis with contrast (CPT® 74177) is not routinely indicated in the initial metastatic staging of pediatric RMS
- > PET is not routinely utilized to assess treatment response in RMS
- > PET is generally not indicated during active treatment for recurrent pediatric cancer
- Residual mass that has not changed in size since the last conventional imaging does not justify PET imaging during surveillance
- PET avidity in a residual mass at the end of planned therapy is not an indication for PET imaging during surveillance

PEDONC-8.3: Non-Rhabdomyosarcoma Soft Tissue Sarcomas (NRSTS)

NRSTS Initial Staging:

- CT with contrast or MRI without and with contrast for primary site imaging of NRSTS arising in the abdomen or pelvis
- CT with contrast is the preferred primary site imaging modality for NRSTS arising in the thoracic cavity (not the chest wall)
- MRI without and with contrast is the preferred primary site imaging modality for NRSTS occurring in all other anatomic locations, including the chest wall
- ➤ CT Chest with (CPT® 71260) **or** CT Chest without contrast (CPT® 71250) for evaluation of lung metastases in the initial workup of all pediatric soft tissue sarcomas and should be completed prior to anesthesia exposure if possible
- Other staging imaging should be deferred until a histologic diagnosis is made:
 - PET/CT (CPT[®] 78815) may be considered in the following:
 - Desmoplastic small round cell tumor
 - Prior to neoadjuvant chemotherapy
 - Evaluating inconclusive findings found on conventional imaging
 - Whole body PET/CT (CPT® 78816) if there is clinical suspicion of skull or distal lower extremity involvement
 - Nuclear bone scan (See: <u>PEDONC-1.3</u> for coding) to evaluate for bony metastases but should be omitted if PET is performed
 - CT Abdomen and Pelvis with contrast (CPT® 74177) in the initial metastatic staging of pediatric NRSTS, only in the following situations:
 - Evaluation of inconclusive PET findings
 - Primary site of abdomen or pelvis
 - Lower extremity primary sites
 - Desmoplastic small round cell tumor
 - MRI Brain (CPT® 70553) and Spine (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) without and with contrast for initial staging in the following pediatric NRSTS:
 - Primary site involving the paraspinal or paravertebral region
 - PET- or nuclear bone scan-avid lesions in skull, neck, vertebrae
 - Neurologic signs or symptoms raising suspicion of CNS metastases

NRSTS Treatment Response:

- ➤ CT Chest with contrast (CPT® 71260) **or** CT Chest without contrast (CPT® 71250) every 2 cycles during treatment **and** at the end of planned therapy
- Primary site imaging:
 - CT with contrast or MRI without and with contrast every 2 cycles during treatment and at the end of planned therapy
 - Restaging imaging after local control surgery (complete or partial resection) is completed
- Metastatic site imaging:
 - Repeat imaging of all known metastatic sites using the same modality as during initial staging whenever primary site imaging is necessary
- > PET imaging only in the following circumstances if positive at initial diagnosis:
 - Assessment prior to local control surgery or radiation therapy
 - Evaluation of residual mass visible on conventional imaging as part of end of therapy evaluation
 - Assessment of disease visible on PET but not conventional imaging
 - Once PET has been documented to be negative for a given individual's cancer or all PET-avid disease has been surgically resected, PET should only be used for continued disease monitoring or surveillance when one of the exceptions in section PEDONC-1: General Guidelines applies.
 - PET imaging during active treatment for recurrent pediatric cancer may be indicated in rare circumstances when results are likely to result in a treatment change for the individual, including a change from active treatment to surveillance.

NRSTS Surveillance Imaging:

- All individuals with localized NRSTS:
 - Individuals treated with chemotherapy:
 - CT with contrast or MRI without and with contrast of primary site every 6 months for 5 years after completion of all therapy
 - Individuals who did NOT receive chemotherapy (individuals who underwent resection with or without radiation):
 - CT with contrast or MRI without and with contrast of primary site every 3 months for the first 12 months, then every 6 months in years 2-5 to complete 5 years surveillance after completion of therapy
 - ◆ CT Chest with (CPT® 71260) **or** CT Chest without contrast (CPT® 71250) every 6 months for 3 years after completion of all therapy. Chest x-ray is supported in years 4 and 5, with CT only supported for new symptoms or new findings on chest x-ray.

- All individuals with metastatic NRSTS:
 - CT with contrast or MRI without and with contrast of primary site every 6 months for 5 years after completion of all therapy
 - CT Chest with (CPT® 71260) or CT Chest without contrast (CPT® 71250) for individuals with no prior history of disease in the chest
 - For individuals with KNOWN prior history of metastatic disease in the chest, CT Chest with (CPT® 71260) or without contrast (CPT® 71250) every 6 months for 5 years.
 - CT with contrast of all known metastatic sites every 6 months for 5 years after completion of all therapy
 - Nuclear bone scan (See: <u>PEDONC-1.3</u> for coding) should be used for surveillance of known bony metastases every 6 months for 5 years after completion of all therapy
- Surveillance after recurrence:
 - CT Chest with contrast (CPT® 71260), and CT Chest with contrast or MRI without and with contrast of the primary site following successful treatment for recurrent NRSTS every 3 months for 1 year after completing therapy for recurrence
 - Surveillance imaging more than 12 months after completing therapy for recurrence should follow the standard timing listed in this surveillance section
- > PET for surveillance imaging of NRSTS only when one of the following applies:
 - Conventional imaging (CT, MRI, US, plain film) reveals findings that are inconclusive or suspicious for recurrence, and PET avidity will determine whether biopsy or continued observation is appropriate
 - Rare circumstances where obvious clinical symptoms show strong evidence suggesting recurrence and PET would replace conventional imaging modalities.

- All soft tissue sarcomas other than RMS fall into this category
- Because soft tissue sarcomas can arise from any soft tissue, the presenting symptoms and primary tumor sites vary widely and strongly influence the appropriate imaging decisions
- CT Abdomen and Pelvis with contrast (CPT® 74177) is not routinely indicated in the initial metastatic staging of pediatric NRSTS
- Many individuals with NRSTS will be treated with surgical resection alone, and these individuals enter immediately into surveillance
- > PET imaging is not routinely utilized to assess treatment response in NRSTS
- PET imaging is generally not indicated during active treatment for recurrent pediatric cancer.
- Residual mass that has not changed in size since the last conventional imaging does not justify PET
- PET avidity in a residual mass at the end of planned therapy is not an indication for PET imaging during surveillance

PEDONC-9: Bone Tumors	
PEDONC-9.1: Bone Tumors – General Considerations	143
PEDONC-9.2: Benign Bone Tumors	144
PEDONC-9.3: Osteogenic Sarcoma (OS)	146
PEDONC-9.4: Ewing Sarcoma Family of Tumors (ESFT), Include	ling
Primitive Neuroectodermal Tumors (PNET)	151

PEDONC-9.1: Bone Tumors – General Considerations

These guidelines include both benign and malignant lesions.

- Unless specified below, individuals who are <18 years old should be imaged according to this guideline section. Exceptions include:</p>
 - Osteogenic sarcoma individuals of all ages should be imaged according to guidelines in PEDONC-9.3: Osteogenic Sarcoma (OS)
 - Ewing sarcoma and Primitive Neuroectodermal Tumor individuals of all ages should be imaged according to guidelines in <u>PEDONC-9.4: Ewing Sarcoma</u> <u>Family of Tumors (ESFT), Including Primitive Neuroectodermal Tumors</u> (PNET)
 - Chondrosarcoma individuals of all ages should be imaged according to guidelines in <u>ONC-12.6: Bone Sarcomas-Initial Workup/Staging</u> in the Oncology Imaging Guidelines
 - Chordoma individuals of all ages should be imaged according to guidelines in ONC-12.6: Bone Sarcomas-Initial Workup/Staging in the Oncology Imaging Guidelines
 - Giant cell tumor of bone and enchondroma individuals of all ages should be imaged according to guidelines in <u>ONC-12.9</u>: <u>Benign Bone Tumors-General</u> <u>Considerations</u> in the Oncology Imaging Guidelines
 - Other benign bone tumor individuals of all ages should be imaged according to guidelines in PEDONC-9.2: Benign Bone Tumors
- Prosthetic devices for children after surgery for bony tumors are nearly all customized.
 - CT, contrast as requested in alignment with prosthetic manufacturer specifications, is appropriate when requested by the operating surgeon for planning for customized-to-patient joint replacement or prosthetic surgery
- > All bone tumors should be evaluated by plain x-ray prior to any advanced imaging
- Where indications for PET/CT are noted, please note that indications and coding for rare circumstances where PET/MRI may be approved are found in <u>PEDONC-1.4:</u> <u>PET Imaging in Pediatric Oncology</u>
- CT Chest is superior to PET/CT for the detection of pulmonary metastases, and is indicated in the initial workup of all suspected malignant bone tumors.
 - CT Chest should be completed prior to anesthesia exposure, if possible.

PEDONC-9.2: Benign Bone Tumors

Osteochondroma

Indication	Imaging Study
Preoperative planning	 MRI without and with contrast can be approved after evaluation by the operating surgeon See: PEDONC-9.1: General Considerations for requests related to prosthetic planning
 ANY of the following: Concern for malignant transformation New or worsening pain/symptoms Change on a recent plain x-ray 	MRI without contrast or without and with contrast

Osteoid osteoma

Indication	Imaging Study
Suspected, based on clinical history and plain film findings	> CT without contrast
 ANY of the following: CTs are not characteristic for diagnosis Individual has bone pain not localized to the area of findings on CT or x-ray 	 ONE of the following: Triple phase bone scan (CPT® 78315) SPECT (CPT® 78803) Hybrid SPECT/CT (CPT® 78830)
Individuals with new pain who have been previously treated with radiofrequency ablation of curettage	 Bone scan (CPT® 78830, CPT® 78315, or CPT® 78803 – as requested)

> Other benign tumors

 Variety of diagnoses, including osteoblastoma, aneurysmal bone cysts, fibrous dysplasia, chondroblastoma and others

Indication	Imaging Study
Plain x-ray is non-diagnostic	MRI without and with contrast
Preoperative planning	 MRI without and with contrast OR CT (contrast as requested) after evaluation by the operating surgeon
Surveillance	> Plain x-ray
 ANY of the following: New findings on plain x-ray New/worsening clinical symptoms not explained by recent plain x-ray 	MRI without and with contrast

Pediatric Oncology Imaging Guidelines

- Plain x-ray appearance is diagnostic for many benign bone tumors, and advanced imaging is generally unnecessary except for preoperative planning
- ➤ Plain x-ray appearance is diagnostic for osteochondroma for the majority of individuals and advanced imaging is generally unnecessary

PEDONC-9.3: Osteogenic Sarcoma (OS)

Indication	Imaging Study
Suspected or Biopsy Proven Diagnosis	 MRI without and with contrast of the primary site OR CT, contrast as request, of the primary site if there is a contraindication to MRI AND CT Chest with (CPT® 71260) or without (CPT® 71250) contrast CT Chest is indicated in initial workup of all suspected malignant bone tumors in children and should be completed prior to anesthesia exposure if possible These studies may be approved even
	when PET/CT has already been authorized or performed
Initial Staging of Biopsy Proven Disease	 PET/CT whole body (CPT® 78816) Nuclear bone scan (see: PEDONC-1.3 for coding) may be substituted if PET not available PET/CT may be approved in addition to the convetional imaging listed in the suspected/diagnosis sections CT Abdomen and Pelvis with contrast (CPT® 74177) is not routinely indicated in the initial metastatic staging of pediatric OS, but can be approved in the following situations: Evaluation of inconclusive PET findings Primary site of abdomen or pelvis
Suspected bony metastatic sites noted on PET or bone scan	 MRI without and with contrast of the suspected metastatic site OR CT with contrast of the suspected metastatic site
Restaging after 10 to 12 weeks of neoadjuvant chemotherapy prior to local control surgery	 MRI without and with contrast of primary site CT Chest with (CPT® 71260) or without (CPT® 71250) contrast PET/CT whole body (CPT® 78816) or bone scan (see: PEDONC-1.3 for coding)

Indication	Imaging Study
Individuals with metastatic disease undergoing current chemotherapy	 CT Chest with (CPT® 71260) or without (CPT® 71250) contrast can be performed every 2 cycles during treatment and at the end of planned chemotherapy MRI without and with contrast of primary site can be performed every 2 cycles during treatment and at the end of planned chemotherapy If previously positive for bony metastases, PET/CT whole body (CPT® 78816) or bone scan (See: PEDONC-1.3 for coding) every 2 cycles during treatment and at the end of planned chemotherapy Imaging may be indicated more frequently around the time of surgical resection of primary or metastatic lesions to assess for resectability
Preoperative planning for local control surgery	 CT, contrast as requested MRA and/or CTA may rarely be indicated for complicated surgical resections, and can be approved after evaluation by the operating surgeon to clarify inconclusive MRI findings for preoperative planning See: PEDONC-9.1: General Considerations for advancing imaging requests related to prosthetic planning

Indication	Imaging Study
Following local control surgery, until the end of planned adjuvant chemotherapy	 MRI without and with contrast of primary site ~6 weeks after surgical procedure, and at the end of planned chemotherapy Plain x-rays of the primary site and chest immediately after local control and then every 2 months between the supported, listed advanced imaging studies. CT Chest with (CPT® 71260) or without (CPT® 71250) contrast: Measurable pulmonary metastases: every 6 weeks, and at the end of planned chemotherapy No measurable pulmonary metastases: every 4 months, and at the end of planned chemotherapy Bone scan (See: PEDONC-1.3 for coding) every 4 months, and at the end of planned chemotherapy PET/CT whole body (CPT® 78816) can be used in place of bone scan, if positive for distant bone metastases at initial diagnosis
Recurrent metastatic or recurrent unresectable disease on treatment	 The following may be approved every 2 cycles of treatment, and at the end of planned chemotherapy: CT Chest with (CPT® 71260) or without (CPT® 71250) contrast MRI without and with contrast of primary site can be performed every 2 cycles during treatment and at the end of planned chemotherapy PET is generally not indicated during active treatment for recurrent pediatric cancer. In rare circumstances, PET imaging with CPT® 78816 may be appropriate when results are likely to result in a treatment change for the individual, including a change from active treatment to surveillance.

Indication	Imaging Study
Surveillance (all individuals regardless of primary site)	 CT or MRI as performed during suspected or initial disease workup (provided the individual does not have an endoprosthesis that will cause MRI or CT artifact): Every 3 months for 1 year, then every 4 months for 1 year, then every 6 months for 1 year, then annually for 2 years after completion of all therapy CT Chest with (CPT® 71260) or without (CPT® 71250) contrast every 3 months for 1 year, then every 4 months for 1 year after completion of all therapy After 24 months, chest x-ray (CXR) should be used for pulmonary recurrence surveillance, and CT Chest can be approved to clarify inconclusive CXR findings Bone scan (See: PEDONC-1.3 for coding) every 3 months for 1 year, then every 4 months for 1 year, then every 6 months for 1 year, then annually for 2 years after completion of all therapy
Additional surveillance for individuals with recurrent or metastatic disease	 CT Chest with (CPT® 71260) or without (CPT® 71250) contrast every 3 months for 1 year, then every 4 months for 1 year, then every 6 months for 1 year, then annually for 2 years after completion of all therapy Bone scan (See: PEDONC-1.3 for coding) should be used for evaluation of distant bony metastases every 3 months for 1 year, then every 6 months for 2 years, then annually for 2 years after completion of all therapy

Indication	Imaging Study
 For suspected recurrence, ANY of the following: Conventional imaging reveals findings that are inconclusive or suspicious for recurrence and PET avidity will determine whether biopsy or continued observation is appropriate Rare circumstances where obvious clinical symptoms show strong evidence suggesting recurrence and PET would replace conventional imaging modalities 	➤ PET/CT If PET is approved in osteosarcoma, it should be whole body PET/CT (CPT® 78816)
Biopsy proven recurrence	 Refer to initial imaging section studies for suspected recurrence PET/CT whole body (CPT® 78816) may be approved for biopsy proven recurrence If disease is considered potentially resectable, follow osteosarcoma treatment response as previous

Pediatric Oncology Imaging Guidelines

PEDONC-9.4: Ewing Sarcoma Family of Tumors (ESFT), Including Primitive Neuroectodermal Tumors (PNET)

Primitive Neuroectodermai Tumors	(FNCI)
Indication	Imaging Study
Suspected/Diagnosis – ill-defined or non- discrete soft tissue mass without bony involvement	> US (CPT® 76881 or CPT® 76882)
Suspected or Biopsy Proven Diagnosis – Primary site	 MRI without and with contrast CT, contrast as requested, if there is a contraindication to MRI MRA and/or CTA may rarely be indicated for complicated surgical resections, and can be approved after evaluation by the operating surgeon to clarify inconclusive MRI findings for preoperative planning CT Chest with (CPT® 71260) or without (CPT® 71250) contrast CT Chest is indicated in initial workup of all suspected or confirmed malignant bone tumors in children and should be completed prior to anesthesia exposure if possible These studies may be approved even when PET/CT has already been authorized or performed
Suspected or Biopsy Proven Diagnosis – Chest wall primary	 MRI Chest without and with contrast AND CT Chest with (CPT® 71260) or without (CPT® 71250) contrast ◆ CT Chest is indicated in initial workup of all suspected or confirmed malignant bone tumors in children and should be completed prior to anesthesia exposure if possible These studies may be approved even when PET/CT has already been
Initial Staging (additional imaging after biopsy confirmed disease)	authorized or performed ➤ PET/CT whole body (CPT® 78816) ◆ Bone scan (See: PEDONC-1.3 for coding) may be substituted for PET imaging if PET not available ◆ PET/CT may be approved in addition to the conventional imaging listed in the suspected/diagnosis sections
 For ANY of the following: Evaluation of inconclusive PET findings Primary site involving the abdomen or pelvis 	CT Abdomen and Pelvis with contrast (CPT® 74177)

Indication	Imaging Study
Restaging after 10 to 12 weeks of neoadjuvant chemotherapy prior to local control surgery	 MRI without and with contrast of the primary site CT (contrast as requested) may be approved if requested per valuation by the operating surgeon for pre-operative
	planning ◆ See: PEDONC-9.1: Bone Tumors - General Considerations for imaging requests related to prosthetic planning
	 CT Chest with (CPT® 71260) or without (CPT® 71250) contrast PET/CT whole body (CPT® 78816) or
	bone scan (See: PEDONC-1.3 for coding)
Treatment response following local control	MRI without and with contrast of primary site 3 months after surgical procedure and at the end of planned chemotherapy
	 Plain x-rays of the primary site and chest immediately after local control then every 3 months
	 CT Chest with (CPT® 71260) or without (CPT® 71250) contrast
surgery	 Measurable pulmonary metastases: every 6 weeks and at the end of planned chemotherapy
	 No measurable pulmonary metastases: every 3 months and at the end of planned chemotherapy
	PET/CT whole body (CPT® 78816) or bone scan (See: PEDONC-1.3 for coding) at the end of planned chemotherapy
Individuals with metastatic disease undergoing current chemotherapy	 CT Chest with (CPT® 71260) or without (CPT® 71250) contrast can be performed
	every 2 cycles during treatment and at the end of planned chemotherapy
	MRI without and with contrast of primary site can be performed every 2 cycles during treatment and at the end of
	 planned chemotherapy If previously positive for bony metastases, PET/CT whole body (CPT® 78816) or
	bone scan (See: <u>PEDONC-1.3</u> for coding) every 2 cycles during treatment and at the end of planned chemotherapy
	 Imaging may be indicated more frequently around the time of surgical resection of primary or metastatic lesions to assess for resectability

Indication	Imaging Study
Recurrent metastatic or recurrent unresectable disease on treatment	 The following may be approved every 2 cycles of treatment, and at the end of planned chemotherapy: CT Chest with (CPT® 71260) or without (CPT® 71250) contrast MRI without and with contrast of primary site can be performed every 2 cycles during treatment and at the end of planned chemotherapy PET is generally not indicated during active treatment for recurrent pediatric cancer. In rare circumstances, PET imaging may be appropriate when results are likely to result in a treatment change for the individual, including a change from active treatment to surveillance.
Surveillance – any primary site	 Plain x-rays AND MRI without and with contrast OR CT with contrast of the primary tumor site: Every 3 months for 1 year, then every 4 months for 1 year, then every 6 months for 1 year, then annually for 2 years after completion of all therapy Bone scan (See: PEDONC-1.3 for coding) every 3 months for one year, then every 4 months for one year, and then annually for 2 years after completion of all therapy CT Chest with (CPT® 71260) or without (CPT® 71250) contrast every 3 months for 1 year then every 4 months for 1 year after completion of all therapy Individuals with metastatic or recurrent ESFT may have CT Chest annually for an additional two years (for a total of four years of surveillance) For individuals with localized ESFT, Chest x-ray (CXR) should be used for pulmonary recurrence surveillance after the initial 24 months of surveillance, and CT Chest can be approved to clarify inconclusive CXR findings
For suspected recurrence, ANY of the following:	> PET/CT whole body (CPT® 78816)

Indication	Imaging Study
 Conventional imaging reveals findings that are inconclusive or suspicious for recurrence and PET avidity will determine whether biopsy or continued observation is appropriate Rare circumstances where obvious clinical symptoms show strong evidence suggesting recurrence and PET would replace conventional imaging modalities 	
Biopsy proven recurrence	 Refer to ESFT initial imaging for studies for suspected recurrence. PET/CT whole body (CPT® 78816) If disease is considered potentially resectable, follow ESFT treatment response as previously noted

- ➤ Bone and bone marrow metastases can occur in ESFT and cause a significant change in treatment approach
- PET/CT can replace bone scan and bone marrow biopsy in ESFT individuals and is indicated in the initial staging of all ESFT individuals after histologic diagnosis is established

PEDONC-10: Pediat	ric Germ Cell Tumors
Indication	Imaging Study
Initial staging	 CT Abdomen and Pelvis with contrast (CPT® 74177) Testicular primary tumors can defer abdominal imaging until after histologic confirmation at the discretion of the operating surgeon CT Chest with contrast (CPT® 71260) Should be completed prior to anesthesia exposure if possible
Clarify inconclusive initial staging CT findings or for a known contraindication to CT contrast	MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197)
Additional initial evaluation for individuals with symptoms suggesting CNS metastases	 MRI Brain without and with contrast (CPT[®] 70553)
Additional initial evaluation for individuals with systemic symptoms or bone pain	Nuclear bone scan (See: PEDONC-1.3 for coding)
Restaging in individuals with disease not completely resected at initial diagnosis	 Every 2 cycles (~every 6 weeks) and at the end of planned therapy: CT Chest/Abdomen/Pelvis (CPT® 71260 and CPT® 74177) with contrast CT imaging may be indicated more frequently to assess for surgical resectability in individuals who have received more than 4 cycles of chemotherapy Imaging of any metastatic sites with the same modality used during initial staging
 Suspicious lesion seen on CT and BOTH of the following: Relapse risk is determined to be low by the treating physician Biopsy would cause unnecessary morbidity for the individual 	 Short-interval CT study of the involved area can be approved
Surveillance, individuals with normal (not elevated) tumor markers at the time of diagnosis	CT Abdomen and Pelvis with contrast (CPT® 74177) every 6 months for 2 years, then every 12 months for 3 years to complete a total of 5 years of surveillance

Indication	Imaging Study
Stage I individuals age 0-10 years treated with surgery only	 Chest x-ray should be completed every 3 months for 1 year after completion of all therapy For those with primary mediastinal tumors at diagnosis, CT Chest with contrast (CPT® 71260) should be approved in lieu of CXR according to the above schedule. CT Abdomen and Pelvis with contrast (CPT® 74177) every 3 months for 1 year
Stage I individuals ages 11+ years treated with surgery only	 Chest x-ray should be completed every 4 months for 2 years, then every 6 months for 1 year, then every 12 months for 1 year to complete 4 years surveillance imaging after completion of all therapy. For individuals with primary mediastinal tumors at diagnosis, CT Chest with contrast (CPT® 71260) should be approved in lieu of chest x-ray on the above schedule. CT Abdomen and Pelvis with contrast (CPT® 74177) every 4 months for 2 years, then every 6 months for 1 year, then in 12 months to complete 4 years surveillance
Stage II-IV individuals	 Chest x-ray should be completed every 6 months for 2 years then every 12 months for 1 year after completion of all therapy. For individuals with primary mediastinal tumors at diagnosis, CT Chest with contrast (CPT® 71260) should be approved in lieu of chest x-ray on the above schedule. CT Abdomen and Pelvis with contrast (CPT® 74177) every 6 months for 2 years, then in 12 months to complete 3 years surveillance Individuals with brain or bone metastases should have surveillance imaging on the same schedule as the primary site imaging with the same modality used during initial staging.

Indication	lmaging Study
 Suspected recurrence: Any clinically significant rise in tumor markers Symptoms suggesting recurrent disease Abnormal chest x-ray 	CT Chest/Abdomen/Pelvis with contrast (CPT® 71260 and CPT® 74177)

Background and Supporting Information

General Considerations:

- Malignant pediatric germ cell tumors commonly include one of four histologic subtypes:
 - Yolk sac tumor
 - Choriocarcinoma
 - Embryonal carcinoma
 - Mixed histology
- Tumors can occur in testicular, ovarian or extragonadal primary locations
- Ovarian masses that are <10 cm in size, have minimal or no visible solid component on ultrasound, and have normal tumor markers are almost universally benign teratomas or functional cysts
 - Advanced imaging is not necessary
- Sex cord stromal tumors (granulosa cell, theca, sertoli, and leydig tumors) are rare in pediatrics and should be imaged according to general guidelines in: <u>ONC-20:</u> <u>Testicular, Ovarian and Extragonadal Germ Cell Tumors</u> in the Oncology Imaging Guidelines.
- ➤ This section applies to primary germ cell tumors occurring outside the central nervous system in children who are ≤15 years old at the time of initial diagnosis.
 - For individuals who are >15 years old at diagnosis, the overall prognosis is inferior and these individuals should be imaged according to general guidelines in: <u>ONC-20: Testicular, Ovarian and Extragonadal Germ Cell Tumors</u> in the Oncology Imaging Guidelines.
- For CNS germ cell tumors, use the imaging guidelines in: <u>PEDONC-4.7: CNS</u>
 <u>Germinomas and Non-Germinomatous Germ Cell Tumors (NGGCT)</u>.

Treatment Considerations:

- Overall treatment strategies are similar for all malignant germ cell tumors.
- Individuals with localized GCT are often cured with surgery alone and do not receive adjuvant therapy.
 - These individuals should be imaged using surveillance guidelines after surgery is completed.
- Individuals receiving adjuvant chemotherapy are usually treated with 4 to 6 cycles of combination chemotherapy.

Imaging Modality Considerations:

- Initial evaluation of: Ovarian, testicular, and abdominal extragonadal suspected GCT should be completed by ultrasound and tumor markers (AFP, β-hCG)
 - Once a primary mass suspected to be GCT is discovered, initial staging is indicated prior to histologic confirmation
 - The degree of abdominal exploration and node sampling necessary for adequate staging is determined in part by imaging findings and is required for preoperative planning
- The primary method of response assessment is by tumor marker decrease
- The primary method of surveillance in pediatric GCT is frequent assessment of serum tumor markers, unless tumor markers were not elevated at diagnosis
- Surveillance imaging of the chest in disease stages I-IV should generally be performed using chest x-ray
 - See surveillance indications for specific imaging recommendations
- There has been no published evidence to date supporting the routine use of PET/CT in the evaluation of pediatric GCT
 - Additionally, PET has been found to have similar efficacy to CT imaging in initial staging of adults with non-seminomatous GCT (the majority of pediatric GCT are non-seminomatous)
- PET as a marker of treatment response has been shown not to be predictive of individual outcomes in GCT and should not be approved
 - Suspicious lesions seen on conventional imaging should be biopsied to confirm active disease

PEDONC-11: Pediatric Liver Tumors	
PEDONC-11.1: Pediatric Liver Tumors – General Considerations	162
PEDONC-11.2: Hepatoblastoma	163
PEDONC-11.3: Pediatric Hepatocellular Carcinoma (HCC)	166

PEDONC-11.1: Pediatric Liver Tumors – General Considerations

- Primary hepatic germ cell tumors should follow imaging guidelines in: <u>PEDONC-10:</u> <u>Pediatric Germ Cell Tumors</u>
- > Primary hepatic sarcomas should follow imaging guidelines in: PEDONC-8.3: Non-Rhabdomyosarcoma Soft Tissue Sarcomas (NRSTS)
- ➤ Imaging requests relating to liver transplant surgery and surveillance should follow guidelines in: <u>AB-42: Transplant</u> in the Abdomen Imaging Guidelines

PEDONC-11.2: Hepatoblastoma

Hepatoblastoma Initial Staging:

- Ultrasound imaging for most suspected liver tumors as initial evaluation
- Ultrasound may be approved even after MRI or CT imaging in order to allow evaluation for tumor thrombus
- Once a primary liver mass is discovered, definitive imaging prior to histologic diagnosis may involve ANY of the following:
 - MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) is preferred for evaluating tumor margins and vascular anatomy
 - ◆ CT Abdomen and Pelvis with contrast (CPT® 74177)
 - MRI and CT imaging for some tumors during initial evaluation
 - MRA Abdomen (CPT® 74185) or CTA Abdomen (CPT® 74175) to evaluate vascular invasion
- CT Chest with (CPT® 71260) or CT Chest without contrast (CPT® 71250) in the initial workup of all pediatric liver tumors and should be completed prior to anesthesia exposure if possible
- ➤ Bone scan (See: <u>PEDONC-1.3: Modality General Considerations</u>) for initial evaluation of bony metastases only with systemic symptoms or bone pain.
- MRI Brain without and with contrast (CPT® 70553) only for symptoms suggesting CNS metastases
- ➤ PET/CT only in very rare circumstances for preoperative planning when MRI and CT scans are insufficient for surgical decision making.
 - Indications and coding for rare circumstances where PET/MRI may be approved are found in PEDONC-1.4: PET Imaging in Pediatric Oncology

Hepatoblastoma Treatment Response:

- ➤ CT Chest with (CPT® 71260) **or** CT Chest without contrast (CPT® 71250) every 2 cycles **and** at the end of planned therapy for individuals with incomplete resection at initial diagnosis
- ➤ CT Abdomen and Pelvis with contrast (CPT® 74177) **or** MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) every 2 cycles **and** at the end of planned therapy for individuals with incomplete resection at initial diagnosis
 - While the majority of individuals will require abdomen and pelvis imaging at all time points, the pelvis imaging may be omitted at the discretion of the ordering physician
 - MRA Abdomen (CPT® 74185) or CTA Abdomen (CPT® 74175) to evaluate vascular invasion
- Imaging of any metastatic sites with the same modality used during initial staging every 2 cycles and at the end of planned therapy for individuals with incomplete resection at initial diagnosis

- Imaging more frequently to assess for surgical resectability in individuals who have received more than 4 cycles of chemotherapy
- Abdominal ultrasound if tumor thrombus was detected at initial diagnosis.
 - If no tumor thrombus was present, continued ultrasound evaluations are only indicated with a specific reason documented in the clinical records
- PET/CT should only be considered in very rare circumstances for preoperative planning when MRI and CT scans are insufficient for surgical decision making.

Hepatoblastoma Surveillance Imaging:

- ➤ For surveillance in individuals with an AFP of >100 ng/mL
 - CT Chest and Abdomen with contrast (CPT® 71260 and CPT® 74160) for any clinically significant rise in tumor markers or symptoms suggesting recurrent disease
- ➤ For individuals with AFP ≤100 ng/mL at diagnosis or recurrence, the following imaging is appropriate:
 - ◆ CT Abdomen with contrast (CPT® 74160) every 3 months for 2 years, then every 4 months for 2 years after completion of all therapy
 - Chest x-ray or CT Chest with contrast (CPT® 71260) every 3 months for 2 years, then every 4 months for 2 years after completion of all therapy
 - Individuals with brain or bone metastases should have surveillance imaging on the same schedule as the primary site imaging with the same modality used during initial staging

- ➤ Pediatric liver tumors primarily include hepatoblastoma and hepatocellular carcinoma, but hepatic germ cell tumors and primary hepatic sarcomas occur with some frequency. Tumor markers are useful for initial evaluation as well as treatment response, particularly in hepatoblastoma. Early consideration of liver transplant may be undertaken in children and adolescents with unresectable localized disease, provided that the disease remains confined to the liver.
- Hepatoblastoma occurs most commonly in very young children (median diagnosis age of 19 months). Most cases of hepatoblastoma are sporadic, but some are associated with genetic abnormalities, including Beckwith-Wiedemann syndrome, familial adenomatous polyposis, and trisomy 18. Most suspected liver tumors will have ultrasound and tumor markers (AFP, β-hCG, CEA) as part of the initial evaluation.
- There has been no published evidence to date supporting the routine use of PET/CT imaging in the evaluation of pediatric hepatoblastoma during initial imaging, treatment response, or surveillance.
- > PET/CT should not be approved in lieu of biopsy of suspicious lesions

- Individuals with localized hepatoblastoma of pure fetal histology are often cured with surgery alone and do not receive adjuvant therapy. These individuals should be imaged using surveillance guidelines after surgery is completed.
- Individuals receiving adjuvant chemotherapy are usually treated with 2 to 8 cycles of combination chemotherapy. Tumor marker decrease is important in response assessment but does not eliminate the need for advanced imaging in individuals with unresected hepatoblastoma.
- The primary method of surveillance in hepatoblastoma is frequent assessment of serum tumor markers (primarily AFP).
- ➤ No specific imaging for surveillance in individuals with an AFP of >100 ng/mL at diagnosis or recurrence.

PEDONC-11.3: Pediatric Hepatocellular Carcinoma (HCC)

Pediatric HCC Initial Staging:

- Ultrasound for most suspected liver tumors as initial evaluation
- Ultrasound may be approved even after MRI or CT imaging in order to allow evaluation for tumor thrombus
- Once a primary liver mass is discovered, definitive imaging prior to histologic diagnosis including ANY of the following:
 - ◆ CT Abdomen and Pelvis with contrast (CPT® 74177)
 - MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197)
 - Some tumors may require both MRI and CT during initial evaluation
 - MRA Abdomen (CPT® 74185) or CTA Abdomen (CPT® 74175) to evaluate vascular invasion
- CT Chest with (CPT® 71260) or CT Chest without contrast (CPT® 71250) in the initial workup of all pediatric liver tumors and should be completed prior to anesthesia exposure if possible
- MRI Brain without and with contrast (CPT® 70553) only for symptoms suggesting CNS metastases
- Nuclear bone scan (See: <u>PEDONC-1.3: Modality General Considerations</u>) for initial evaluation of bony metastases only in individuals with systemic symptoms or bone pain
- ➤ PET/CT should only be considered in very rare circumstances for preoperative planning when MRI and CT are insufficient for surgical decision making.
 - Indications and coding for rare circumstances where PET/MRI may be approved are found in <u>PEDONC-1.4: PET Imaging in Pediatric Oncology</u>

Pediatric HCC Treatment Response:

- ➤ For individuals with disease not completely resected at initial diagnosis, the following every 2 cycles (~6 weeks) **and** at the end of planned therapy:
 - ◆ CT Chest with (CPT® 71260) **or** CT Chest without contrast (CPT® 71250)
 - CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197)
 - While the majority of individuals will require abdomen and pelvis imaging at all time points, the pelvis imaging may be omitted at the discretion of the ordering physician
 - MRA (CPT® 74185) or CTA (CPT® 74175) Abdomen to evaluate vascular invasion.
- Imaging of any metastatic sites with the same modality used during initial staging
- Abdominal ultrasound if tumor thrombus was detected at initial diagnosis

- If no tumor thrombus was present, continued ultrasound evaluations are only indicated with a specific reason documented in the clinical records
- PET/CT in very rare circumstances for preoperative planning when MRI and CT scans are insufficient for surgical decision making.

Pediatric HCC Surveillance Imaging:

- ➤ CT Abdomen and Pelvis with contrast (CPT® 74177) every 3 months for 1 year, then every 6 months for 1 year, then annually for 3 years after completion of all therapy
- Chest x-ray or CT Chest with contrast (CPT® 71260) every 3 months for 1 year, then every 6 months for 1 year, then annually for 3 years months after completion of all therapy

- Individuals with brain or bone metastases should have surveillance imaging on the same schedule as the primary site imaging with the same modality used during initial staging.
- HCC, including its rare histologically distinct variant fibrolamellar hepatocellular carcinoma (FL-HCC), occurs mostly in older children and adolescents. Despite recent advances in treatment, overall survival of pediatric HCC diagnosed in advanced stages remains exceedingly poor, with five-year survival of only 17% to 22% for all stages of pediatric HCC (and FL-HCC). Most suspected liver tumors will have ultrasound and tumor markers (AFP, β-hCG, CEA) as initial evaluation.
- PET/CT should not be approved in lieu of biopsy of suspicious lesions
- The majority of hepatocellular carcinoma individuals are treated with surgery alone and do not receive adjuvant therapy. Individuals with successful upfront gross total resection should be imaged using surveillance guidelines after surgery is completed.
- PET/CT has no documented role in the surveillance evaluation of pediatric hepatocellular carcinoma.

PEDONC-12: Retinoblastoma	
PEDONC-12.1: Retinoblastoma – General Considerations	170
PEDONC-12.2: Retinoblastoma - Imaging	171

PEDONC-12.1: Retinoblastoma – General Considerations

- Retinoblastoma (RB) is primarily a disease of the infant and young child, and presents with leukocoria (loss of red reflex).
- About 75% of individuals are diagnosed before the age of two years (bilateral RB presents at 12 months of age).
- Retinoblastoma can occur as heritable (25% of cases) or nonheritable (75%) disease.
 - Heritable RB is associated with a germline mutation in the RB1 gene often resulting typically in bilateral disease.
 - Individuals who carry the RB1 mutation also have increased risk of developing other cancers, such as osteosarcoma, soft tissue sarcomas, or melanoma. For more information on heritable retinoblastoma, see: <u>PEDONC-2.12: Familial</u> <u>Retinoblastoma Syndrome.</u>
 - Whole body MRI has shown poor sensitivity and specificity in individuals with predisposition to systemic malignancy due to germline RB1 mutations, and is not supported.
- Detailed evaluation by a physician with significant training and/or experience in retinoblastoma (most commonly a pediatric ophthalmologist or pediatric oncologist) prior to considering advanced imaging
- Retinoblastoma can be unilateral, bilateral, or trilateral (involving the pineal gland). Extraocular spread of retinoblastoma is rare and generally confined to the brain.

PEDONC-12.2: Retinoblastoma - Imaging

Retinoblastoma Initial Staging

- Tumor biopsy is NOT required prior to imaging
- MRI Orbits (CPT® 70543) and Brain (CPT® 70553) without and with contrast in the initial workup
 - Brain imaging may be omitted or deferred at the discretion of the treating ophthalmologist or oncologist
- ➤ MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) if there is evidence of CNS metastasis on:
 - Ophthalmologic exam
 - MRI Brain
 - Lumbar CSF cytology
- CT Chest (CPT® 71260) and MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) with clinical symptoms to suggest metastatic disease
- CT Orbital (contrast as requested) and Orbital ultrasound if ordered by the treating ophthalmologist for a specified indication
- Nuclear bone scan (See: <u>PEDONC-1.3: Modality General Considerations</u>) is the preferred imaging modality for systemic bone pain suggestive of bony metastases

Retinoblastoma Treatment Response:

- ▶ MRI Orbits (CPT® 70543) and/or Brain (CPT® 70553) every 2 cycles (~ every 6 weeks) and at the end of planned therapy
- ➤ For individuals with metastatic disease, imaging of known positive areas using the same modality at initial staging every 2 cycles (~ 6 to 8 weeks) **and** at the end of planned therapy

Retinoblastoma Surveillance:

- Surveillance using advanced imaging for unilateral retinoblastoma after enucleation or exenteration only for evaluation of specific clinical concerns.
- MRI Orbits (CPT® 70543) and Brain (CPT® 70553) for individuals undergoing ocular salvage treatment approaches every 6 months for 2 years following completion of therapy
- ➤ MRI Brain without and with contrast (CPT® 70553) every 6 months for 5 years from the time of diagnosis with retinoblastoma

Background and Supporting Information

- CT should generally be avoided in retinoblastoma individuals under one year of age or with family history of retinoblastoma (heritable) due to substantially increased risks for secondary malignancy
- PET has no documented role in the evaluation of retinoblastoma
- The primary method of surveillance in retinoblastoma is examination under anesthesia (EUA). Although some older children can be sufficiently evaluated by exam without anesthesia (EWA).
- Surveillance using advanced imaging is generally not indicated for unilateral retinoblastoma after enucleation or exenteration, but can be approved for evaluation of specific clinical concerns.
- Individuals with bilateral retinoblastoma or germline mutation in RB1 are at increased risk for subsequent pineoblastoma
- Routine MRI follow up for pineal disease is not currently supported by evidence in unilateral retinoblastoma individuals without germline RB1 mutations

PEDONC-13: Pediatric Nasopharyngeal Carcinoma	
PEDONC-13.1: Pediatric Nasopharyngeal Carcinoma – General	
Considerations	174
PEDONC-13.2: Pediatric NPC Imaging	175

<u>PEDONC-13.1: Pediatric Nasopharyngeal Carcinoma – General</u> Considerations

- Pediatric nasopharyngeal carcinoma (NPC) is rare in comparison to adult NPC but is responsible for up to 50% of nasopharyngeal cancers in children and has higher rates of aggressive type III EBV-associated histology than adult NPC
- Standard upfront treatment in pediatric NPC consists of 3 to 4 cycles of neoadjuvant chemotherapy followed by definitive chemoradiotherapy. Rare individuals with lower stage disease may be treated with radiotherapy alone

PEDONC-13.2: Pediatric NPC Imaging

Pediatric NPC Initial Staging:

- MRI Brain without and with contrast (CPT® 70553) and MRI Neck without and with contrast (CPT® 70543)
 - CT Head without and with contrast (CPT® 70470), CT Maxillofacial without and with contrast (CPT® 70488), and/or CT Neck with contrast (CPT® 70491) for individuals with documented contraindication to MRI imaging (avoidance of sedation should not be the sole reason)
- CT Chest with contrast (CPT® 71260) in initial staging
- Whole body PET/CT (CPT® 78816) after histologic confirmation of NPC to evaluate for distant metastases
 - Bone scan when PET/CT is unavailable (See: <u>PEDONC-1.3: Modality General</u> Considerations)
 - Indications and coding for rare circumstances where PET/MRI may be approved are found in <u>PEDONC-1.4</u>: <u>PET Imaging in Pediatric Oncology</u>
 - CT Abdomen with contrast (CPT® 74160) for ANY of the following if PET/CT unavailable:
 - Initial EBV DNA load >4000 copies/mL
 - Signs and symptoms of liver disease (including abdominal pain and elevated LFTs)

<u>Pediatric NPC Treatment Response</u>:

- ➤ MRI Brain without and with contrast (CPT® 70553) **and** MRI Neck without and with contrast (CPT® 70543) for response assessment at the following time points:
 - Following completion of neoadjuvant chemotherapy
 - Following completion of chemoradiotherapy
- ➤ CT Chest with contrast (CPT® 71260) and Whole body PET/CT (CPT® 78816) or bone scan (See: <u>PEDONC-1.3: Modality General Considerations</u>) at the following time points:
 - Following completion of neoadjuvant chemotherapy, only if positive at initial diagnosis
 - Following completion of chemoradiotherapy
- PET during active treatment for recurrent pediatric cancer in rare circumstances when results are likely to result in a treatment change, including a change from active treatment to surveillance.

Pediatric NPC Surveillance:

- ➤ MRI Brain without and with contrast (CPT® 70553) **and** MRI Neck without and with contrast (CPT® 70543) every 3 months for 1 year, then every 6 months for 2 years after completion of all planned therapy
- CT Chest with contrast (CPT® 71260) every 3 months for 1 year, then every 6 months for 2 years after completion of all planned therapy

<u>Pediatric NPC Suspected Recurrence:</u>

- MRI Brain without and with contrast (CPT® 70553) and MRI Neck without and with contrast (CPT® 70543)
 - CT Head without and with contrast (CPT® 70470), CT Maxillofacial without and with contrast (CPT® 70488), and/or CT Neck with contrast (CPT® 70491) can be approved for individuals with documented contraindication to MRI imaging
- > CT Chest with contrast (CPT® 71260)
- Whole body PET/CT (CPT® 78816) or bone scan (See: <u>PEDONC-1.3: Modality General Considerations</u>) for histologically confirmed recurrence of NPC. These studies may also be approved for:
 - Clarification of specified inconclusive findings seen on conventional imaging
 - Restaging to identify sites of disease when EBV PCR levels are abnormally high and conventional imaging is negative

- Metastasis frequently occurs in cervical lymph nodes and retropharyngeal space. Distal metastasis usually appears in bones, lungs, mediastinum, and rarely, in the liver. In many individuals, the initial presentation is a cervical adenopathy, and diagnosis is made with a lymph node biopsy.
- Quantitative EBV DNA PCR measured at initial diagnosis can serve as an effective tumor marker if elevated at initial diagnosis.
- Skull base invasion is common in pediatric NPC and has a dramatic impact on prognosis, and is more easily recognized on MRI imaging
- > PET is generally not indicated during active treatment for recurrent pediatric cancer
 - Whole body PET/CT (CPT® 78816) or bone scan (See: <u>PEDONC-1.3: Modality</u> <u>General Considerations</u>) are not indicated for routine surveillance in asymptomatic individuals

PEDONC-14.2: Pediatric ACC - Imaging	180

<u>PEDONC-14.1: Pediatric Adrenocortical Carcinoma – General</u> Considerations

- Pediatric Adrenocortical Carcinoma (ACC) is a rare but aggressive tumor, with fewer than 25 cases diagnosed each year.
- Most individuals are diagnosed because of virilizing symptoms, Cushing syndrome, and rarely with feminization and hyperaldosteronism or detection on screening imaging recommended for specified cancer predisposition syndromes.
- See: <u>PEDONC-2.2: Li-Fraumeni Syndrome (LFS)</u> and <u>PEDONC-2.4: Beckwith-Wiedemann Syndrome (BWS)</u> for screening recommendations for individuals known to have these syndromes.

Pediatric Oncology Imaging Guidelines

PEDONC-14.2: Pediatric ACC - Imaging

Indication Imaging Study		
Initial staging	 CT Chest without contrast (CPT® 71250) or with (CPT® 71260) contrast CT Abdomen without and with contrast (CPT® 74170) or MRI Abdomen without and with contrast (CPT® 74183) Nuclear bone scan (See: PEDONC-1.3 for coding) 	
After complete resection, with no plans for chemotherapy or radiotherapy	See surveillance below	
Restaging, for all unresected primary or metastatic disease on chemotherapy	 Every 2 cycles (~6 weeks) during chemotherapy, and following completion of all planned chemotherapy: CT Chest without contrast (CPT® 71250) or with (CPT® 71260) contrast CT Abdomen without and with contrast (CPT® 74170) or MRI Abdomen without and with contrast (CPT® 74183) If positive for distant metastases at initial diagnosis: Nuclear bone scan (See: PEDONC-1.3 for coding) every 2 cycles (~6 weeks) during chemotherapy and following completion of all planned chemotherapy 	
Response assessment at the completion of radiotherapy	 CT Abdomen without and with contrast (CPT® 74170) or MRI Abdomen without and with contrast (CPT® 74183) 	
Surveillance, individuals with only localized disease at diagnosis	 Every 3 months for 2 years, then every 6 months for 3 years: CT Abdomen without and with contrast (CPT® 74170) or MRI Abdomen without and with contrast (CPT® 74183) 	
Surveillance, individuals with metastatic ACC	 Every 3 months for 2 years, then every 6 months for 3 years: CT Chest without contrast (CPT® 71250) or with (CPT® 71260) contrast CT Abdomen without and with contrast (CPT® 74170) or MRI Abdomen without and with contrast (CPT® 74183) 	
Recurrence	 CT Chest without contrast (CPT® 71250) or with (CPT® 71260) contrast CT Abdomen without and with contrast (CPT® 74170) or MRI Abdomen without and with contrast (CPT® 74183) 	
Suspected bone recurrence	Nuclear bone scan (See: <u>PEDONC-1.3</u> for coding)	

Background and Supporting Information

- The mainstay of treatment is surgery.
 - Chemotherapy, adrenal suppression, and radiotherapy typically follow resection.
 - Many ACC individuals are treated with surgery alone and do not receive adjuvant therapy. These individuals should be imaged using surveillance guidelines after surgery is completed.

PEDONC-15: Pediatric Melanoma and Other Skin Cancers

- ➤ Pediatric melanoma staging is assigned using the American Joint Committee on Cancer (AJCC) staging for adult melanoma. Most cases of melanoma arising in children and AYAs (~75%) are localized at diagnosis, and approximately 90% of individuals with pediatric melanoma are amenable to radical excision. The clinical management of adolescents and young adults with melanoma is still challenging and evolving because it is difficult to diagnose, and there is no standard treatment.
- Non-melanoma skin cancers (mostly basal cell carcinoma and squamous cell carcinoma) are extremely rare in pediatric individuals. In many cases, predisposing factors such as prolonged immunosuppression, radiation therapy, chemotherapy, voriconazole use, or a combination of the factors are present, and established age-specific guidelines for management of these skin tumors do not exist.
- Imaging guidelines and treatment approaches are consistent with those used for adults with melanoma and other skin cancers, and these individuals should follow the imaging guidelines in section <u>ONC-5: Melanomas and Other Skin Cancers</u> in the Oncology Imaging Guidelines.

PEDONC-16: Pediatric Salivary Gland Tumors and Thyroid Tumors

Pediatric Salivary Gland Tumors

- The majority of pediatric salivary gland tumors arise in the parotid gland. Approximately 10 to 15% of tumors arise in the submandibular, sublingual, or minor salivary glands.
- Roughly 75% of pediatric salivary gland tumors are benign, most commonly pleomorphic adenoma.
- The most common malignant tumors occurring in the salivary glands are mucoepidermoid carcinoma, adenoid cystic carcinoma, acinic cell carcinoma, undifferentiated carcinoma, and rarely adenocarcinoma.
- American Joint Committee on Cancer (AJCC) staging is used for pediatric as well as adult salivary gland tumors.
- Imaging and treatment guidelines for malignant pediatric salivary gland tumors are consistent with those used for adults with salivary gland tumors, and these individuals should follow the imaging guidelines in section <u>ONC-4: Salivary Gland</u> <u>Cancers</u> in the Oncology Imaging Guidelines.

Pediatric Thyroid Tumors

- Differentiated thyroid cancers (DTC): Papillary, Follicular and Hurthle Cell are the most common childhood thyroid malignancy. Standard treatment is thyroidectomy and radioactive iodine (RAI).
- Imaging and treatment guidelines for malignant pediatric thyroid tumors are consistent with those used for adults with thyroid tumors, and these patients should follow the imaging guidelines in section **ONC-6: Thyroid Cancers** in the Oncology Imaging Guidelines.

PEDONC-17: Pediatric Breast Masses

- ➤ Ultrasound (CPT® 76641 and CPT® 76642) is the primary and preferred modality used for evaluation of pediatric breast masses.
- MRI has very limited utility in evaluation of pediatric breast masses prior to biopsy, but may be indicated in rare cases for surgical planning when ultrasound is nondiagnostic.
- Pediatric individuals with confirmed breast cancer should be imaged according to section <u>ONC-11: Breast Cancer</u> in the Oncology Imaging Guidelines.

Background and Supporting Information

- Less than 1% of pediatric breast lesions are malignant, and advanced imaging is generally not recommended without histological confirmation of malignancy.
- Mammography has limited utility in pediatric breast mass evaluation due to the high mammographic breast density in this age group, and the risk of the radiation exposure outweighs the benefit of this modality. As a result, mammography is NOT recommended for evaluation of pediatric or adolescent breast masses.
 - BI-RADS classification may overstate the risk of malignancy or need for biopsy in pediatric individuals.

PEDONC-18: Histiocytic Disorders	
PEDONC-18.1: General Considerations	187
PEDONC-18.2: Langerhans Cell Histiocytosis (LCH)	188
PEDONC-18.3: Hemophagocytic Lymphohistiocytosis (HLH)	192
PEDONC-18.4: Non-Langerhans Cell Histiocytoses	193

PEDONC-18.1: General Considerations

- The majority of histiocytic disorders occurring in the pediatric population are either Langerhans Cell Histiocytosis (LCH) or Hemophagocytic Lymphohistiocytosis (HLH).
- The Non-Langerhans cell histiocytoses encompass a variety of diseases, and have limited imaging considerations except as specified later in this section.
- Where there are indications for PET/CT in these guidelines, please note that indications and coding for rare circumstances where PET/MRI may be approved are found in <u>PEDONC-1.4: PET Imaging in Pediatric Oncology</u>

PEDONC-18.2: Langerhans Cell Histiocytosis (LCH)

LCH Initial imaging studies:

- Chest x-ray (CXR)
- ➤ Abdominal ultrasound (CPT® 76700) with attention to liver and spleen
- Skeletal survey
- ➤ MRI Brain without and with contrast (CPT® 70553) for ANY of the following:
 - Headaches or visual or neurologic disturbances
 - Polyuria/polydipsia or other endocrine abnormalities
 - Skull or craniofacial (including jaw) bone involvement
 - Otorrhea or hearing loss (CT Temporal Bone may be substituted if requested)
 - Other signs or symptoms suggesting intracranial involvement, including neurodegeneration syndrome
- CTA/MRA Head (CPT® 70496/CPT® 70544) may be approved as part of operative planning or image guidance
- CT Chest with (CPT® 71260) or without contrast (CPT® 71250) for ANY of the following:
 - Abnormal CXR
 - Symptoms of pulmonary involvement and normal CXR
- ➤ CT Abdomen and/or Pelvis with contrast (CPT® 74177, 74160, or 72193) for any of the following, if PET/CT has not been performed:
 - Abdominal and/or pelvic signs and symptoms
 - Abdominal and/or pelvic findings on ultrasound
- ➤ MRI Abdomen without and with contrast (CPT® 74183) for ANY of the following:
 - Elevated liver function tests (usually >5X upper limit of normal)
 - Abnormalities seen on abdominal ultrasound or CT
- ➤ MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) for ANY of the following:
 - Vertebral lesions seen on skeletal survey
 - Clinical symptoms (including back pain) suggesting spinal involvement and negative skeletal survey
- ➤ Whole body PET/CT (CPT® 78816) may be approved for ANY of the following:
 - At baseline to assess for multisite disease in pediatric patients (<age 18 years)
 - Multifocal bone involvement suspected on skeletal survey or other studies
 - Findings equivocal for multisite involvement on other imaging studies
 - Bone pain and negative skeletal survey
 - Involvement of high risk sites: CNS, liver, spleen, or bone marrow
 - Other clinical symptoms suggesting multisite disease
 - ◆ If a PET/CT is performed, additional diagnostic CTs are not generally supported except in the scenario of pulmonary LCH.
- ➤ Whole body Tc-99m bone scan (CPT® 78306) can be approved in lieu of PET for the same indications if PET is unavailable

LCH Treatment Response:

- Both PET/CT and CT with contrast and MRI without and with contrast only for simultaneous treatment response evaluation with specific documentation showing that both are necessary
- CT and/or MRI and/or PET/CT (if modality showed disease at initial diagnosis):
 - After 6 weeks of treatment and after 12 weeks of treatment for those with persistent measurable disease
- ➤ Following the initial phase, treatment response evaluation of **involved sites** with CT with contrast or MRI without and with contrast, every 3 months while receiving active treatment and at completion of therapy.
 - Shorter interval imaging for documented signs or symptoms concerning for disease progression
- At the end of planned therapy:
 - Chest x-ray (CXR)
 - Abdominal ultrasound (CPT® 76700)
 - Skeletal survey
 - Repeat of all additional imaging studies positive at initial workup (except PET)
- PET during active treatment for recurrent pediatric cancer only in rare circumstances when results are likely to result in a treatment change, including a change from active treatment to surveillance.

LCH Surveillance Imaging:

- > Surveillance imaging is determined by areas of disease involvement
 - Bone involvement
 - Plain x-ray of involved bony areas at 6 weeks, then at 3, 6, and 12 months after completion of therapy for individuals with single-site disease. For individuals with multifocal bone disease, additional plain x-ray is supported at 18 and 24 months.
 - CT with contrast, MRI without and with contrast, or PET/CT whole body (CPT[®] 78816) may be approved for suspected bony recurrence on plain x-ray.
 - Skull or craniofacial (including jaw) bone involvement should be imaged according to CNS involvement section below.
- > Pulmonary involvement
 - CT Chest with (CPT[®] 71260) or CT Chest without contrast (CPT[®] 71250) every 6 months for the first 2 years post completion of therapy for any of the following:
 - Individuals with a history of pulmonary involvement
 - Individuals with new respiratory or chest symptoms
 - New findings on CXR

CNS involvement

- MRI Brain without and with contrast (CPT® 70553) at 6 weeks, and then every 6
 months for 2 years after completion of all therapy for previously documented
 measurable intracranial lesions
 - If negative at that time, continued surveillance at 4, 7, and 10 years after completion of all planned therapy
 - If residual measurable intracranial lesions are present at 6 months, imaging every 3 months until negative or unchanged on two consecutive studies, at which time the schedule in the previous bullet should begin
- MRI Brain without and with contrast (CPT® 70553) for documented hypothalamicpituitary dysfunction at every 6 months for 2 years, and at 4, 7, and 10 years after completion of all planned therapy
 - MRI at any time for worsening neurologic symptoms
- Intraspinal lesions should be imaged according to the same guidelines as brain imaging using MRI without and with contrast of all involved spine levels

Liver involvement

- Individuals with a history of liver involvement may have one of the following every
 6 months for 2 years after completion of all therapy:
 - Ultrasound Abdomen (CPT® 76700)
 - CT Abdomen with contrast (CPT[®] 74160)
 - MRI Abdomen with and without contrast (CPT® 74183)
- Suspected recurrence or inconclusive findings on any surveillance imaging
 - All imaging studies supported of initial workup may be approved, including whole body PET/CT (CPT® 78816)

- This guideline may be used for all ages of individuals.
- ➤ LCH includes a heterogeneous group of disorders formerly known by other names including histiocytosis X, eosinophilic granuloma, Letterer-Siwe Disease, Hand-Schuller-Christian Disease, and diffuse reticuloendotheliosis. LCH has a widely variable clinical presentation, ranging from single indolent lesions to disseminated multisystem disease.
- Most common sites of involvement are skin, bones, liver, lung, and pituitary, though other sites are possible
- Individuals with localized or single site disease treated only with local therapies or observed should be imaged according to surveillance guidelines
- Individuals receiving systemic therapy will usually undergo treatment for ~12 months. Treatment response is assessed using any modalities showing disease at initial diagnosis after ~6 weeks of treatment
- Once PET/CT shows no remaining FDG-avid lesions, additional PET imaging is not indicated
- > PET is generally not indicated during active treatment for recurrent pediatric cancer

- Bone involvement
 - Skull or craniofacial (including jaw) bone involvement at diagnosis are at higher risk for CNS recurrence
- CNS involvement
 - CNS LCH has a particularly high rate of refractory and recurrent disease, and requires longer imaging surveillance
- Liver involvement
 - Persistent liver involvement is rare, and imaging after completion of LCH therapy will be highly individualized depending on degree of liver dysfunction and plans for supportive therapy or liver transplant

PEDONC-18.3: Hemophagocytic Lymphohistiocytosis (HLH)

- As imaging for this condition is usually done on an urgent basis, ANY or ALL of the following may be approved for the initial evaluation of HLH include:
 - Ultrasound Abdomen (CPT® 76700)
 - CT Abdomen and/or Pelvis (contrast as requested)
 - MRI Abdomen (CPT® 74183) and/or Pelvis (CPT® 72197) without and with contrast
 - Chest x-ray
 - CT Chest with contrast (CPT® 71260)
 - MRI Brain without and with contrast (CPT® 70553)
 - CTA/MRA Head (CPT® 70496/CPT® 70544) may be approved as part of operative planning or image guidance
- Whole body PET/CT (CPT® 78816) for the purpose of identifying a site for tissue diagnosis of a primary source of infection or malignancy if conventional imaging has been completed and is unrevealing
 - If a malignancy is identified as the inciting factor for HLH, additional imaging decisions for that malignancy should be based on the appropriate diagnosisspecific guidelines

- There are no standard imaging studies required for the diagnosis and initial evaluation of HLH. Most cases are diagnosed with a combination of physical findings, laboratory testing, and bone marrow evaluation. Advanced imaging studies may be necessary to assess organ dysfunction as HLH commonly affects the liver, spleen, and bone marrow, and less commonly the kidneys, lungs, and brain
- ➤ It is NOT required to perform ultrasound or plain film in a stepwise fashion if CT or MRI is planned as individuals with HLH can deteriorate rapidly
- There is no established standard role for PET in the diagnosis or treatment response evaluation of HLH
 - Secondary HLH is very difficult to treat if the primary cause is not concurrently treated

PEDONC-18.4: Non-Langerhans Cell Histiocytoses

<u>Juvenile Xanthogranuloma (JXG):</u>

- Skin and/or cervical nodules:
 - CT with contrast of involved nodal areas
- > Systemic JXG with multi-organ involvement:
 - ◆ MRI Brain (CPT® 70553) **and/or** Orbits (CPT® 70543) without and with contrast
 - CT Neck (CPT® 70491), Chest (CPT® 71260), and/or Abdomen (CPT® 74160) with contrast
 - CTA/MRA Head (CPT® 70496/CPT® 70544) may be approved as part of operative planning or image guidance
- There is no established role for PET in the diagnosis or treatment of JXG

Rosai-Dorfman Disease (RDD):

- > RDD Initial Imaging Studies:
 - ◆ MRI Brain (CPT® 70553) and/or Orbits (CPT® 70543) without and with contrast
 - CTA/MRA Head (CPT® 70496/CPT® 70544) may be approved as part of operative planning or image guidance
 - CT Neck (CPT® 70491), Chest (CPT® 71260) and/or Abdomen and Pelvis (CPT® 74177) with contrast
 - Whole body PET/CT (CPT[®] 78816) after histological confirmation of diagnosis
- RDD Treatment Response:
 - Treatment response imaging can be approved after 2-3 cycles of systemic therapy during active treatment using any modalities showing disease at diagnosis, including PET/CT.
 - Once PET/CT is negative, conventional imaging with other modalities that revealed disease at presentation may be approved for subsequent restaging at completion of chemotherapy and/or radiation and/or after surgical resection.
 - RDD Surveillance Imaging:
 - Surveillance imaging can be approved every 3 months for the first year after completion of treatment, then every 6 months using any modalities showing disease at initial diagnosis excluding PET-CT.
 - PET/CT is not supported for routine surveillance of RDD, but can be approved if conventional imaging is inconclusive for suspected recurrence.

Erdheim-Chester Disease (ECD):

- ECD Initial imaging studies:
 - ◆ MRI Brain (CPT®70553) **and/or** Orbits (CPT®70543) without and with contrast
 - CTA/MRA Head (CPT® 70496/CPT® 70544) may be approved as part of operative planning or image guidance
 - Nuclear bone scan (See <u>PEDONC-1.3: Modality General Considerations</u>)
 - Whole body PET/CT (CPT[®] 78816)
 - CT Neck (CPT® 70491), Chest (CPT® 71260) and/or Abdomen and Pelvis (CPT® 74177) with contrast
 - CTA Chest or MRA Chest (CPT[®] 71275 or CPT[®] 71555) or Abdomen (CPT[®] 74175 or CPT[®] 74185) to evaluate vascular tree involvement
 - Cardiac MRI without and with contrast (CPT[®] 75561)
- > ECD Treatment Response:
 - Treatment response imaging every 3 months during active treatment using any modalities showing disease at initial diagnosis, including PET/CT
 - Once PET/CT shows no remaining FDG-avid lesions, additional PET imaging is only indicated when conventional imaging studies are inconclusive and acute treatment decisions will be made based on PET results.
- ECD Surveillance Imaging:
 - CT and/or MRI and/or Nuclear bone scan and/or CTA and/or MRA and/or Cardiac MRI (if modality showed disease at initial diagnosis) every 3 months for the first year after completion of treatment and then every 6 months
 - PET/CT if conventional imaging is inconclusive for suspected recurrence.

- Non-Langerhans Cell histiocytoses includes diagnoses such as juvenile xanthogranuloma (JXG), sinus histiocytosis with lymphadenopathy (Rosai-Dorfman disease, RDD), and Erdheim-Chester disease (ECD)
- In general, these are localized cutaneous or nodal disease without need for regular advanced imaging, but important exceptions are listed in this section.
- Juvenile Xanthogranuloma (JXG):
 - Generally involves only skin or cervical nodes, and involutes spontaneously
- Rosai-Dorfman Disease (RDD):
 - Characterized by bulky adenopathy (usually cervical) with frequent systemic involvement
 - There is no established role for PET in the diagnosis or treatment of RDD
 - Because of the paucity of evidence for PET, PET/CT should not be used to replace tissue confirmation for any clinical scenario in RDD
 - There is no established role for routine surveillance imaging of asymptomatic individuals after treatment for RDD

Erdheim-Chester Disease (ECD):

- An aggressive histiocytic disorder with overall poor prognosis that is characterized by long bone involvement with frequent spread to multiple organs
- Most individuals will receive systemic therapy
- Once PET/CT shows no remaining FDG-avid lesions, additional PET imaging is not indicated unless conventional imaging studies are inconclusive and acute treatment decisions will be made based on PET results.
- PET/CT is not supported for routine surveillance of ECD

PEDONC-19: Long Term Pediatric Cancer Survivors			
PEDONC-19.1: Long Term Pediatric Cancer Survivors – General			
Considerations	197		
PEDONC-19.2: Cardiotoxicity and Echocardiography	198		
PEDONC-19.3: Second Malignant Neoplasms (SMN)	199		
PEDONC-19.4: Osteonecrosis in Long Term Cancer Survivors	201		
PEDONC-19.5: CNS Vascular Changes In Pediatric Cancer Surviv	vors		
Following CNS Radiation	202		

<u>PEDONC-19.1: Long Term Pediatric Cancer Survivors – General</u> Considerations

- This section applies to individuals who have passed the end of the surveillance imaging period for their specific cancer, or 5 years after completion of therapy, whichever occurs first
- As these are long term survivors, many individuals falling under this guideline section will have reached adult age. However, these guidelines relate specifically to late effects of childhood cancer treatment and should be applied to all long term childhood cancer survivors regardless of current age
- The Children's Oncology Group has published comprehensive guidelines for the management of long-term childhood cancer survivors, and these are available at: http://www.survivorshipquidelines.org
- A summary of cancer treatment should be available for all individuals in this category and should generally include, at minimum:
 - Type of cancer and stage
 - Dates of diagnosis, recurrence, cancer-related surgeries, beginning and end dates of chemotherapy, radiotherapy, and/or stem cell transplant
 - Protocol number used for treatment and cumulative chemotherapy drug dose exposures
 - Cumulative radiation dose, fraction number, modality, and field exposure
- Annual detailed history and complete physical examination is a critical component of cancer survivorship care and along with laboratory testing serves as the primary method of screening for the majority of late effects
- Advanced imaging for asymptomatic screening is not routinely indicated except as specified in this section
- Imaging requests related to new clinical signs or symptoms in a long term cancer survivor not explicitly covered in this section should be reviewed according to the guideline for the individual's cancer type or the relevant non-malignant clinical problem

PEDONC-19.2: Cardiotoxicity and Echocardiography

Screening echocardiography (CPT® 93306, CPT® 93307, or CPT® 93308) for life after exposure to anthracycline chemotherapy, cardiotoxic immunotherapy, or cardiac exposure to radiotherapy

SCREENING ECHOCARDIOGRAM INDICATIONS				
Age at time of Exposure	Cumulative Doxorubicin Equivalent Dose	Cumulative radiation dose to cardiac muscle	Echocardiogram frequency	
All ages	None	None	None	
0-0.99 years	≥250 mg/m²	None	Annual	
	0-249 mg/m ²	Any dose	Annual	
	0-249 mg/m ²	None	Every 2 years	
1-4.99 years	≥250 mg/m²	Any dose	Annual	
	0-249 mg/m ²	15+ Gy	Annual	
		0-14.99 Gy	Every 2 years	
	None	35+ Gy	Annual	
		15-34.99 Gy	Every 2 years	
		0-14.99 Gy	Every 5 years	
5+ years	≥250 mg/m²	Any dose	Every 2 years	
	0-249 mg/m ²	15+ Gy	Every 2 years	
		0-14.99 Gy	Every 5 years	
	None	35+ Gy	Every 2 years	
		None	15-34.99 Gy	Every 5 years
		0-14.99 Gy	None	
All ages with known ventricular dysfunction		Annual		

- Female cancer survivors who are pregnant or planning to become pregnant:
 - Echocardiogram as a baseline exam and in the 3rd trimester, and as clinically indicated for symptoms (see: <u>CD-11.4: Pregnancy – Maternal Imaging</u> in the Cardiology Imaging Guidelines) if ANY of the following are present:
 - Anthracycline or cardiotoxic chemotherapy/immunotherapy exposure
 - Chest radiotherapy

- Exposure to cardiotoxic anthracycline chemotherapy agents is common in pediatric oncology due to the high success rate of this drug class in the treatment of pediatric cancers
- Cardiac risk is assessed based on the age of the individual at the time of treatment initiation the cumulative drug exposure expressed as doxorubicin equivalent mg/m², and the presence of absence of radiotherapy exposure to cardiac muscle.
- Stress echocardiography is not indicated as a screening study for anthracyclines cardiotoxicity in the absence of coronary artery disease symptoms. See: <u>CD-1.4:</u> <u>Stress Testing with Imaging Indications</u> in the Cardiac Imaging Guidelines

PEDONC-19.3: Second Malignant Neoplasms (SMN)

SMN—Breast Cancer:

Clinical breast exam every 6 months supplemented with:

- MRI Breast (CPT® 77049) annually and annual mammogram beginning at age 25 or 8 years after completion of radiotherapy (whichever occurs later – screening breast MRI is not supported prior to age 25) for individuals who received therapeutic radiation exposure in the following fields while they were under 30 years of age:
 - Chest (thorax)
 - Whole lung
 - Mediastinal
 - Axilla
 - Mini-mantle, mantle, or extended mantle
 - ◆ Total (TLI) or subtotal (SLTI) lymphoid irradiation
 - Total body irradiation (TBI)

SMN—CNS Tumors:

- MRI Brain without and with contrast (CPT® 70553) can be approved every 2 years after completion of radiotherapy for individuals with NF1 or NF2
- ➤ MRI Brain without and with contrast (CPT® 70553) for any individual with a history of brain radiotherapy and new neurologic symptoms, including simple headache
- MRI Cervical (CPT® 72156), Thoracic (CPT® 72157), and Lumbar Spine (CPT® 72158) without and with contrast for any individual with a history of spine radiotherapy and new neurologic symptoms, including change in quality of pain
 - MRI Spine with contrast only (Cervical-CPT® 72142, Thoracic-CPT® 72147, Lumbar-CPT® 72149) if being performed immediately following a contrastenhanced MRI Brain
- MRI Brain without and with contrast (CPT® 70553) annually for individuals with history of brain radiotherapy and persistent neurologic symptoms
- MRI Cervical (CPT® 72156), Thoracic (CPT® 72157), and Lumbar Spine (CPT® 72158) without and with contrast annually for individuals with a history of spine radiotherapy and persistent neurologic symptoms
 - MRI Spine with contrast only (Cervical-CPT® 72142, Thoracic-CPT® 72147, Lumbar-CPT® 72149) if being performed immediately following a contrastenhanced MRI Brain

SMN—Colorectal Cancer:

No advanced imaging is currently recommended. See: <u>Background and Supporting Information</u> section for recommended surveillance

- SMN—Breast Cancer:
 - Clinical breast exam every 6 months supplemented with advanced imaging
- SMN-CNS Tumors:
 - These are associated with radiation exposure to the brain and with neurofibromatosis
 - Routine surveillance of asymptomatic individuals with normal neurologic exams is not supported by evidence, with the exception of NF1 and NF2 listed above
- SMN—Colorectal Cancer:
 - Colonoscopy is recommended every 5 years beginning at age 30 or 5 years after radiation exposure (whichever is later) for individuals with ≥30 Gy radiation exposure to the following fields:
 - Thoracic, Lumbar, Sacral, or Whole Spine
 - Abdomen
 - Pelvis
 - Total body irradiation (TBI)
 - Colonoscopy is also recommended every 5 years beginning at age 30 or 5 years after radiation exposure (whichever is later) for individuals with:
 - Personal history of ulcerative colitis, GI malignancy, adenomatous polyps, or hepatoblastoma
 - Familial polyposis
 - Family history of colorectal cancer or polyps in a first degree (parent or sibling) relative
- While the American Cancer Society recently added computed tomographic colonography (CTC) (AKA "Virtual Colonoscopy") as an acceptable option for colorectal cancer screening of average-risk adults, the National Comprehensive Cancer Network and United States Preventive Services Task Force concluded that data was too premature to warrant its use in screening. Colonoscopy remains the preferred screening modality for survivors at highest risk of colorectal cancer

PEDONC-19.4: Osteonecrosis in Long Term Cancer Survivors

- Plain films of symptomatic areas are indicated prior to advanced imaging
- DEXA or Quantitative CT screening only for those with symptoms to suggest bone density issues.
 - DEXA or Quantitative CT screening is generally not recommended until age 18 unless a specific intervention will be planned based on the imaging results.
- Serial advanced imaging is only indicated in osteonecrosis with specific documentation regarding how the advanced imaging will change current management.
 - MRI without contrast of the affected joint(s) when advanced imaging is necessary for acute management decisions
- See: <u>PEDONC-3.2: Acute Lymphoblastic Leukemia (ALL)</u> for information on imaging osteonecrosis in ALL individuals during active treatment.

- Osteonecrosis is associated with corticosteroid, chemotherapy and radiation exposure during treatment for ALL, NHL, and allogeneic HSCT in pediatrics. Osteonecrosis occurs primarily in hips, knees, and ankles and is frequently multifocal.
- ➤ Osteoradionecrosis of the jaw can occur in individuals receiving radiotherapy to the mandible or maxilla; those receiving ≥40 Gy are at highest risk. Although unusual, it can also occur in any bone without symptoms. It is rare in other disease types
- Routine bone density screening using DEXA or Quantitative CT screening has not been well normalized in the pediatric population
- Surveillance imaging of asymptomatic individuals to detect osteonecrosis has not been shown to impact outcomes, and it is not standard to alter treatment based on imaging findings alone without symptoms.
 - Follow up MRI of incidentally discovered osteonecrosis findings in asymptomatic individuals has not been shown to impact individual outcomes and is not necessary

<u>PEDONC-19.5: CNS Vascular Changes In Pediatric Cancer Survivors Following CNS Radiation</u>

- ➤ MRI Brain without and with contrast (CPT® 70553) and MRA Head (CPT® 70544, 70545, or 70546) for all individuals of any age with new neurologic symptoms or headache and a history of cranial irradiation.
- MRI Brain without and with contrast (CPT® 70553) and MRA Head (CPT® 70544, 70545, or 70546) may be approved annually for 10 years post treatment in patients with a history of cranial irradiation and any of the following additional risk factors:
 - Down Syndrome, Sickle cell disease, or Neurofibromatosis 1 or 2
 - Parasellar or suprasellar tumors (i.e. craniopharyngioma)
 - Radiation dose >50 Gy
 - Radiation field involving Circle of Willis

Background and Supporting Information

Children receiving cranial radiation are at increased risk of cerebrovascular complications, including: hemorrhagic and ischemic stroke, moyamoya, occlusive vasculopathy, and cavernomas. These complications may occur months to years after radiation exposure.
